# Principal Component Analysis for Time Series: Segmentation via Contemporaneous Linear Transformation

Qiwei Yao

Department of Statistics, London School of Economics q.yao@lse.ac.uk

### Joint work with Jinyuan Chang University of Melbourne Bin Guo Sichuan University

■ Goal of study:

a high-dim TS  $\rightarrow$  several uncorrelated lower-dim TS

- Methodology: PCA for time series
  - Transformation via an eigenanalysis
  - Permutation

maximum cross correlations

- FDR based on multiple tests

- Real data illustration
- Asymptotic properties in 3 settings:

p fixed,  $p = o(n^c)$ ,  $\log p = o(n^c)$ 

- Simulation
- Segmenting multiple volatility processes

**Goal**: For  $p \times 1$  weakly stationary time series  $y_t$ , search for a contemporaneous linear transformation:

$$\mathbf{y}_t = \mathbf{A}\mathbf{x}_t, \quad \text{or} \quad \mathbf{x}_t = \mathbf{B}\mathbf{y}_t \quad (i.e. \ \mathbf{B} = \mathbf{A}^{-1})$$

such that

$$\mathbf{x}_{t} = \begin{pmatrix} \mathbf{x}_{t}^{(1)} \\ \vdots \\ \mathbf{x}_{t}^{(q)} \end{pmatrix}, \quad \operatorname{Cov}(\mathbf{x}_{t}^{(i)}, \mathbf{x}_{s}^{(j)}) = \mathbf{0} \quad \forall i \neq j \text{ and } t, s.$$

Hence,  $\mathbf{x}_t^{(1)}, \cdots, \mathbf{x}_t^{(q)}$  can be modelled separately!

**Goal**: For  $p \times 1$  weakly stationary time series  $y_t$ , search for a contemporaneous linear transformation:

$$\mathbf{y}_t = \mathbf{A}\mathbf{x}_t, \quad \text{or} \quad \mathbf{x}_t = \mathbf{B}\mathbf{y}_t \quad (i.e. \ \mathbf{B} = \mathbf{A}^{-1})$$

such that

$$\mathbf{x}_{t} = \begin{pmatrix} \mathbf{x}_{t}^{(1)} \\ \vdots \\ \mathbf{x}_{t}^{(q)} \end{pmatrix}, \quad \operatorname{Cov}(\mathbf{x}_{t}^{(i)}, \mathbf{x}_{s}^{(j)}) = \mathbf{0} \quad \forall i \neq j \text{ and } t, s.$$

Hence,  $\mathbf{x}_t^{(1)}, \cdots, \mathbf{x}_t^{(q)}$  can be modelled separately!

- realistic? RealData
- how to find B and  $\mathbf{x}_t$ ?

**Observations**:  $y_1, \dots, y_n$  from a  $_{p \times 1}$  weakly stationary time series **Assumption**:  $y_t = Ax_t$ , and

$$\mathbf{x}_{t} = \begin{pmatrix} \mathbf{x}_{t}^{(1)} \\ \vdots \\ \mathbf{x}_{t}^{(q)} \end{pmatrix}, \quad \operatorname{Cov}(\mathbf{x}_{t}^{(i)}, \mathbf{x}_{s}^{(j)}) = \mathbf{0} \quad \forall i \neq j \text{ and } t, s.$$

Without loss of generality:  $Var(y_t) = Var(x_t) = I_p$ , and thus

 $\mathbf{A}'\mathbf{A} = \mathbf{I}_p, \quad \text{i.e. } \mathbf{A} \text{ is orthogonal}, \quad \mathbf{x}_t = \mathbf{A}'\mathbf{y}_t$ 

Goal: estimate  $\mathbf{A} = (\mathbf{A}_1, \cdots, \mathbf{A}_q)$ , or more precisely,  $\mathcal{M}(\mathbf{A}_1), \cdots$ ,  $\mathcal{M}(\mathbf{A}_q)$ , as  $\widehat{\mathbf{x}}_t^{(j)} = \widehat{\mathbf{A}}'_j \mathbf{y}_t, \ j = 1, \cdots, q$ .

Note.  $(\mathbf{A}, \mathbf{x}_t)$  can be replaced by  $(\mathbf{AH}, \mathbf{H}'\mathbf{x}_t)$  for any  $\mathbf{H} = \operatorname{diag}(\mathbf{H}_1, \cdots, \mathbf{H}_q)$  with  $\mathbf{H}'_i\mathbf{H}_j = \mathbf{I}_{p_j}$ 

#### **Step 1: Transformation via eigenanalysis**

Notation:  $\Sigma_y(k) = \operatorname{Cov}(\mathbf{y}_{t+k}, \mathbf{y}_t), \quad \Sigma_x(k) = \operatorname{Cov}(\mathbf{x}_{t+k}, \mathbf{x}_t),$   $\mathbf{W}_y = \sum_{k=0}^{k_0} \Sigma_y(k) \Sigma_y(k)' = \mathbf{I}_p + \sum_{k=1}^{k_0} \Sigma_y(k) \Sigma_y(k)',$  $\mathbf{W}_x = \sum_{k=0}^{k_0} \Sigma_x(k) \Sigma_x(k)' = \mathbf{I}_p + \sum_{k=1}^{k_0} \Sigma_x(k) \Sigma_x(k)'.$ 

#### **Step 1: Transformation via eigenanalysis**

Notation:  $\Sigma_y(k) = \operatorname{Cov}(\mathbf{y}_{t+k}, \mathbf{y}_t), \quad \Sigma_x(k) = \operatorname{Cov}(\mathbf{x}_{t+k}, \mathbf{x}_t),$   $\mathbf{W}_y = \sum_{k=0}^{k_0} \Sigma_y(k) \Sigma_y(k)' = \mathbf{I}_p + \sum_{k=1}^{k_0} \Sigma_y(k) \Sigma_y(k)',$  $\mathbf{W}_x = \sum_{k=0}^{k_0} \Sigma_x(k) \Sigma_x(k)' = \mathbf{I}_p + \sum_{k=1}^{k_0} \Sigma_x(k) \Sigma_x(k)'.$ 

As 
$$\Sigma_y(k) = \mathbf{A}\Sigma_x(k)\mathbf{A}'$$
,  $\mathbf{W}_y = \mathbf{A}\mathbf{W}_x\mathbf{A}'$ .

#### **Step 1: Transformation via eigenanalysis**

Notation:  $\Sigma_y(k) = \operatorname{Cov}(\mathbf{y}_{t+k}, \mathbf{y}_t), \quad \Sigma_x(k) = \operatorname{Cov}(\mathbf{x}_{t+k}, \mathbf{x}_t),$   $\mathbf{W}_y = \sum_{k=0}^{k_0} \Sigma_y(k) \Sigma_y(k)' = \mathbf{I}_p + \sum_{k=1}^{k_0} \Sigma_y(k) \Sigma_y(k)',$  $\mathbf{W}_x = \sum_{k=0}^{k_0} \Sigma_x(k) \Sigma_x(k)' = \mathbf{I}_p + \sum_{k=1}^{k_0} \Sigma_x(k) \Sigma_x(k)'.$ 

As 
$$\Sigma_y(k) = \mathbf{A}\Sigma_x(k)\mathbf{A}'$$
,  $\mathbf{W}_y = \mathbf{A}\mathbf{W}_x\mathbf{A}'$ .

Eigenanalysis:  $\mathbf{W}_x \mathbf{\Gamma}_x = \mathbf{\Gamma}_x \mathbf{D}$ , columns of  $\mathbf{\Gamma}_x$  are eigenvectors of  $\mathbf{W}_x$  with the eigenvalues in diagonal matrix  $\mathbf{D}$ .

 $\mathbf{W}_{y}\mathbf{A}\mathbf{\Gamma}_{x} = \mathbf{A}\mathbf{W}_{x}\mathbf{A}'\mathbf{A}\mathbf{\Gamma}_{x} = \mathbf{A}\mathbf{W}_{x}\mathbf{\Gamma}_{x} = \mathbf{A}\mathbf{\Gamma}_{x}\mathbf{D}$ 

Thus  $\Gamma_y = \mathbf{A}\Gamma_x$ , and  $\Gamma'_y \mathbf{y}_t = \Gamma'_x \mathbf{A}' \mathbf{y}_t = \Gamma'_x \mathbf{x}_t$ .

Note  $\mathbf{W}_x = \operatorname{diag}(\mathbf{W}_{x,1}, \cdots, \mathbf{W}_{x,q})$ 

**Proposition 1.** (i)  $\Gamma_x$  can be taken with the same block-diagonal structure as  $\mathbf{W}_x$ .

(ii) Any  $\Gamma_x$  is a column-permutation of  $\Gamma_x$  described in (i), provided

 $\lambda(\mathbf{W}_{x,i}) \neq \lambda(\mathbf{W}_{x,j})$  for any  $i \neq j$ .

Note  $\mathbf{W}_x = \operatorname{diag}(\mathbf{W}_{x,1}, \cdots, \mathbf{W}_{x,q})$ 

**Proposition 1.** (i)  $\Gamma_x$  can be taken with the same block-diagonal structure as  $W_x$ .

(ii) Any  $\Gamma_x$  is a column-permutation of  $\Gamma_x$  described in (i), provided  $\lambda(\mathbf{W}_{x,i}) \neq \lambda(\mathbf{W}_{x,j})$  for any  $i \neq j$ .

For  $\Gamma_x$  specified in (i),  $\Gamma'_x \mathbf{x}_t$  is segmented exactly the same as  $\mathbf{x}_t$ 

Note  $\mathbf{W}_x = \operatorname{diag}(\mathbf{W}_{x,1}, \cdots, \mathbf{W}_{x,q})$ 

**Proposition 1.** (i)  $\Gamma_x$  can be taken with the same block-diagonal structure as  $W_x$ .

(ii) Any  $\Gamma_x$  is a column-permutation of  $\Gamma_x$  described in (i), provided  $\lambda(\mathbf{W}_{x,i}) \neq \lambda(\mathbf{W}_{x,j})$  for any  $i \neq j$ .

For  $\Gamma_x$  specified in (i),  $\Gamma'_x \mathbf{x}_t$  is segmented exactly the same as  $\mathbf{x}_t$ 

Let

$$\widehat{\mathbf{W}}_y = \mathbf{I}_p + \sum_{k=1}^{k_0} \widehat{\mathbf{\Sigma}}_y(k) \widehat{\mathbf{\Sigma}}_y(k)', \qquad \widehat{\mathbf{W}}_y \widehat{\mathbf{\Gamma}}_y = \widehat{\mathbf{\Gamma}}_y \widehat{\mathbf{D}}.$$

Then  $\widehat{\mathbf{z}}_t = \widehat{\Gamma}'_y \mathbf{y}_t$  – require permute components of  $\widehat{\mathbf{z}}_t$  to obtain  $\widehat{\mathbf{x}}_t$ 

#### **Permutation**

**Goal**: put the connected components of  $\widehat{\mathbf{z}}_t = \widehat{\Gamma}'_y \mathbf{y}_t$  together.

Visual examination of CCF if *p* is not large!

Two component series of  $\hat{z}_t$  is <u>connected</u> if the multiple null hypothesis

 $H_0: \rho(k) = 0$  for any  $k = 0, \pm 1, \pm 2, \dots, \pm m$ 

is rejected, where  $\rho(k)$  is cross correlation between two series at lag k.

Permutation is performed as follows:

- i. Start with p groups: each containing one component of  $\widehat{\mathbf{z}}_t$ .
- ii. Combine the two groups together if one connected pair are split over two groups.
- iii. Repeat Step ii above until all connected components are within one group.

#### **Permutation Method I: Max CCF**

Put 
$$\widehat{\mathbf{z}}_t = (\widehat{z}_{1,t}, \cdots, \widehat{z}_{p,t})'$$
.

Let  $\hat{\rho}_{i,j}(h)$  be the sample CCF of  $(\hat{z}_{i,t}, \hat{z}_{j,t})$  at lag h, and

$$\widehat{L}_n(i,j) = \max_{|h| \le m} |\widehat{\rho}_{i,j}(h)|,$$

reject  $H_0$  for the pair  $(\widehat{z}_{i,t}, \widehat{z}_{j,t})$  for large values of  $\widehat{L}_n(i, j)$ .

#### **Permutation Method I: Max CCF**

Put 
$$\widehat{\mathbf{z}}_t = (\widehat{z}_{1,t}, \cdots, \widehat{z}_{p,t})'$$
.

Let  $\hat{\rho}_{i,j}(h)$  be the sample CCF of  $(\hat{z}_{i,t}, \hat{z}_{j,t})$  at lag h, and

$$\widehat{L}_n(i,j) = \max_{|h| \le m} |\widehat{\rho}_{i,j}(h)|,$$

reject  $H_0$  for the pair  $(\hat{z}_{i,t}, \hat{z}_{j,t})$  for large values of  $\hat{L}_n(i, j)$ . Line up  $\hat{L}_n(i, j)$ ,  $1 \le i < j \le p$ , in the descending order:  $\hat{L}_1 \ge \cdots \ge \hat{L}_{p_0}$ ,  $p_0 = p(p-1)/2$ .

Define

$$\widehat{r} = \arg \max_{1 \le j < c_0 p_0} \widehat{L}_j / \widehat{L}_{j+1}, \qquad c_0 \in (0, 1).$$

Reject  $H_0$  for the pairs corresponding to  $\widehat{L}_1, \cdots, \widehat{L}_{\widehat{r}}$ 

*Graph representation*: Let vertexes  $\widehat{V} = \{1, \dots, p\}$  stand for the components of  $\widehat{z}_t = \widehat{\Gamma}' y_t$ , and

 $\widehat{E}_n = \{ \text{edge connecting } i \text{ and } j : \widehat{z}_{i,t}, \widehat{z}_{j,t} \text{ are connected} \}.$ 

Let  $V = \{1, \dots, p\}$  stand for the components of  $\mathbf{z}_t = \mathbf{\Gamma}' \mathbf{y}_t$ , and

$$E = \{ \text{edge connecting } i \text{ and } j : \max_{-m \le h \le m} |\operatorname{Corr}(z_{i,t+h}, z_{j,t})| > 0 \}.$$

Graph representation: Let vertexes  $\widehat{V} = \{1, \dots, p\}$  stand for the components of  $\widehat{\mathbf{z}}_t = \widehat{\Gamma}' \mathbf{v}_t$ , and  $\widehat{E}_n = \{ \text{edge connecting } i \text{ and } j : \widehat{z}_{i,t}, \widehat{z}_{j,t} \text{ are connected} \}.$ Let  $V = \{1, \dots, p\}$  stand for the components of  $\mathbf{z}_t = \mathbf{\Gamma}' \mathbf{y}_t$ , and  $E = \{ \text{edge connecting } i \text{ and } j : \max_{-m \le h \le m} |\operatorname{Corr}(z_{i,t+h}, z_{j,t})| > 0 \}.$ Let  $\varpi = \min_{i \neq j} \min |\lambda(\mathbf{W}_{x,i}) - \lambda(\mathbf{W}_{x,j})|$ ,  $\max_{1 \le i < j \le p} \max_{|h| \le m} |\operatorname{Corr}(z_{i,t+h}, z_{j,t})| > 0, \quad \min_{1 \le i < j \le p} \max_{|h| \le m} |\operatorname{Corr}(z_{i,t+h}, z_{j,t})| = 0,$  $\widehat{r} = \arg \max_{1 \le j \le p_0} (\widehat{L}_j + \delta_n) / (\widehat{L}_{j+1} + \delta_n).$ Proposition 2. As  $n \to \infty$ ,  $\delta_n \to 0$ ,  $\frac{1}{22} \|\widehat{\mathbf{W}}_y - \mathbf{W}_y\|_2 = o(\delta_n)$ , and  $\log p = o(n^{\alpha})$ . Then  $P(\widehat{E}_n = E) \to 1$ .

#### **Prewhitening**

To make CCF for different pairs comparable, prewhiten each component series of  $\widehat{\mathbf{z}}_t = \widehat{\Gamma}'_y \mathbf{y}_t$  separately first.

#### Prewhitening

To make CCF for different pairs comparable, prewhiten each component series of  $\widehat{\mathbf{z}}_t = \widehat{\Gamma}'_y \mathbf{y}_t$  separately first.

(i) If ρ<sub>i,j</sub>(h) = 0, ρ̂<sub>i,j</sub>(h) ~ N(0, 1/n) asymptotically, provided at least one of x<sub>i,t</sub> and x<sub>j,t</sub> is white noise.
(ii) For h ≠ k, ρ̂<sub>i,j</sub>(h), ρ̂<sub>i,j</sub>(k) are asymptotically independent, and Cov{ρ̂<sub>i,j</sub>(h), ρ̂<sub>i,j</sub>(k)} = o<sub>P</sub>(1/n), provided both x<sub>i,t</sub> and x<sub>j,t</sub> are white noise.

Brockwell & Davis (1996, Corollary 7.3.1).

#### Prewhitening

To make CCF for different pairs comparable, prewhiten each component series of  $\widehat{\mathbf{z}}_t = \widehat{\Gamma}'_y \mathbf{y}_t$  separately first.

(i) If ρ<sub>i,j</sub>(h) = 0, ρ̂<sub>i,j</sub>(h) ~ N(0, 1/n) asymptotically, provided at least one of x<sub>i,t</sub> and x<sub>j,t</sub> is white noise.
(ii) For h ≠ k, ρ̂<sub>i,j</sub>(h), ρ̂<sub>i,j</sub>(k) are asymptotically independent, and Cov{ρ̂<sub>i,j</sub>(h), ρ̂<sub>i,j</sub>(k)} = o<sub>P</sub>(1/n), provided both x<sub>i,t</sub> and x<sub>j,t</sub> are white noise.

Brockwell & Davis (1996, Corollary 7.3.1).

In practice, we filter out the autocorrelation for each component series of  $\hat{z}_t$  by fitting an AR with the order determined by AIC and not greater than 5.

To fix the idea, let  $\xi_t$ ,  $\eta_t$  be two WN,  $\rho(k) = \operatorname{Corr}(\xi_{t+k}, \eta_t) = 0$ ,

$$\widehat{\rho}(k) = \sum_{t=1}^{n-k} (\xi_{t+k} - \bar{\xi}) (\eta_t - \bar{\eta}) \Big/ \Big\{ \sum_{t=1}^n (\xi_t - \bar{\xi})^2 \sum_{t=1}^n (\eta_t - \bar{\eta})^2 \Big\}^{1/2}.$$

Asymptotically  $\widehat{\rho}(k) \sim N(0, 1/n)$ , and  $\widehat{\rho}(k), \widehat{\rho}(h)$  are independent.

To fix the idea, let  $\xi_t$ ,  $\eta_t$  be two WN,  $\rho(k) = \operatorname{Corr}(\xi_{t+k}, \eta_t) = 0$ ,

$$\widehat{\rho}(k) = \sum_{t=1}^{n-k} (\xi_{t+k} - \bar{\xi}) (\eta_t - \bar{\eta}) \Big/ \Big\{ \sum_{t=1}^n (\xi_t - \bar{\xi})^2 \sum_{t=1}^n (\eta_t - \bar{\eta})^2 \Big\}^{1/2}$$

Asymptotically  $\widehat{\rho}(k) \sim N(0, 1/n)$ , and  $\widehat{\rho}(k), \widehat{\rho}(h)$  are independent.

The *P*-value for testing  $\rho(k) = 0$  (simple) is  $p_k = 2\Phi(-\sqrt{n}|\hat{\rho}(k)|)$ 

To fix the idea, let  $\xi_t$ ,  $\eta_t$  be two WN,  $\rho(k) = \operatorname{Corr}(\xi_{t+k}, \eta_t) = 0$ ,

$$\widehat{\rho}(k) = \sum_{t=1}^{n-k} (\xi_{t+k} - \bar{\xi}) (\eta_t - \bar{\eta}) \Big/ \Big\{ \sum_{t=1}^n (\xi_t - \bar{\xi})^2 \sum_{t=1}^n (\eta_t - \bar{\eta})^2 \Big\}^{1/2}$$

Asymptotically  $\hat{\rho}(k) \sim N(0, 1/n)$ , and  $\hat{\rho}(k), \hat{\rho}(h)$  are independent. The *P*-value for testing  $\rho(k) = 0$  (simple) is  $p_k = 2\Phi(-\sqrt{n}|\hat{\rho}(k)|)$ Let  $p_{(1)} \leq \cdots \leq p_{(2m+1)}$  be the order statistics of  $\{p_k, |k| \leq m\}$ .

Simes (1986): For  $H_0: \rho(k) = 0, \forall |k| \le m$ , a multiple test rejects  $H_0$  at the level  $\alpha$  if

 $p_{(j)} \leq j\alpha/(2m+1)$  for at least one  $1 \leq j \leq 2m+1$ 

To fix the idea, let  $\xi_t$ ,  $\eta_t$  be two WN,  $\rho(k) = \operatorname{Corr}(\xi_{t+k}, \eta_t) = 0$ ,

$$\widehat{\rho}(k) = \sum_{t=1}^{n-k} (\xi_{t+k} - \bar{\xi}) (\eta_t - \bar{\eta}) \Big/ \Big\{ \sum_{t=1}^n (\xi_t - \bar{\xi})^2 \sum_{t=1}^n (\eta_t - \bar{\eta})^2 \Big\}^{1/2}$$

Asymptotically  $\hat{\rho}(k) \sim N(0, 1/n)$ , and  $\hat{\rho}(k), \hat{\rho}(h)$  are independent. The *P*-value for testing  $\rho(k) = 0$  (simple) is  $p_k = 2\Phi(-\sqrt{n}|\hat{\rho}(k)|)$ 

Let  $p_{(1)} \leq \cdots \leq p_{(2m+1)}$  be the order statistics of  $\{p_k, |k| \leq m\}$ . Simes (1986): For  $H_0 : \rho(k) = 0, \forall |k| \leq m$ , a multiple test rejects  $H_0$  at the level  $\alpha$  if

 $p_{(j)} \leq j\alpha/(2m+1)$  for at least one  $1 \leq j \leq 2m+1$ 

The *P*-value for the multiple test is

$$\begin{split} P &= \min\{\alpha > 0: p_{(j)} \leq j\alpha/(2m+1) \text{ for some } 1 \leq j \leq 2m+1\} \\ &= \min_{1 \leq j \leq 2m+1} p_{(j)} \, (2m+1)/j. \end{split}$$

For each pair components of  $\widehat{\mathbf{z}}_t = \widehat{\mathbf{\Gamma}}'_y \mathbf{y}_t$ , we test multiple hypothesis  $H_0$ , obtaining *P*-value  $P_{i,j}$  for  $1 \le i < j \le q$ .

Arranging those *P*-values in ascending order:

 $P_{(1)} \le P_{(2)} \le \dots \le P_{(p_0)}, \qquad p_0 = p(p-1)/2$ 

**FDR**: For a given small  $\beta \in (0, 1)$ , let

$$\widehat{d} = \max\{k : 1 \le k \le p_0, \ P_{(k)} \le k\beta/p_0\},\$$

and rejects the hypothesis  $H_0$  for the  $\hat{d}$  pairs of the components of  $\mathbf{z}_t$  corresponding to the *P*-values  $P_{(1)}, \dots, P_{(\hat{d})}$ 

For each pair components of  $\widehat{\mathbf{z}}_t = \widehat{\mathbf{\Gamma}}'_y \mathbf{y}_t$ , we test multiple hypothesis  $H_0$ , obtaining *P*-value  $P_{i,j}$  for  $1 \le i < j \le q$ .

Arranging those *P*-values in ascending order:

 $P_{(1)} \le P_{(2)} \le \dots \le P_{(p_0)}, \qquad p_0 = p(p-1)/2$ 

**FDR**: For a given small  $\beta \in (0, 1)$ , let

$$\widehat{d} = \max\{k : 1 \le k \le p_0, \ P_{(k)} \le k\beta/p_0\},\$$

and rejects the hypothesis  $H_0$  for the  $\hat{d}$  pairs of the components of  $\mathbf{z}_t$  corresponding to the *P*-values  $P_{(1)}, \dots, P_{(\hat{d})}$ 

(i) The *P*-values  $p_k$  (|k| < m) are asymptotically independent

(ii) The *P*-values  $P_{i,j}$  ( $1 \le j \le p$ ) are not independent, causing difficulties in choosing  $\beta$  in FDR.

(iii) Ranking the pairwise dependences among the components of  $\hat{z}_t$ .

#### **Real data examples**

# **Example 1**. Monthly temperatures in 1954 - 1998 in p = 7 cities in Eastern China.

Longitude

#### **Time series plots of monthly temperatures in 7 cities**

#### **CCF of monthly temperatures in 7 cities**

– p.15

	-0.703	0.324	-0.617	0.189	0.633	0.499	-0.323
	0.375	1.544	-1.615	0.170	-2.266	0.126	1.596
$\widehat{\mathbf{B}} =$	3.025	-1.381	-0.787	-1.691	-0.212	1.188	-0.165
	-0.197	-1.820	-1.416	3.269	.301	-1.438	1.299
	-0.584	-0.354	0.847	-1.262	-0.218	-0.151	1.831
	1.869	-0.742	0.034	0.501	0.492	-2.533	0.339

Note.  $\widehat{\mathbf{B}} = \widehat{\Gamma}'_y \widehat{\Sigma}_y(0)^{-1/2}$ .

n = 540, p = 7Used  $k_0 = 5$  (in defining  $W_y$ ), hardly changed for  $2 \le k_0 \le 36$ .

#### **CCF for transformed monthly temperatures**

- Visual examination of CCF: {1, 2, 3}, {4}, {5}, {6} and {7}
- Permutation based on max-CCF: the same grouping with  $2 \le m \le 30$
- Permutation based on FDR: the same grouping with  $2 \le m \le 30$  and  $\beta \in [0.001\%, 1\%]$ .

7-dim time series  $\rightarrow$  5 uncorrelated time series

Methodology

#### **Post-Sample Forecast**

Forecasting based on segmentation: fit each subseries of  $\mathbf{x}_t$  with a VAR model, forecast  $\mathbf{x}_t$  based on the fitted models, the forecasts for  $\mathbf{y}_t$  are obtained via  $\mathbf{y}_t = \widehat{\mathbf{B}}^{-1}\mathbf{x}_t$ .

Compare with the forecasts based on fitting a VAR and a restricted VAR (RVAR) directly to  $y_t$ .

Implementation: using VAR in *R*-package vars

For each of the last 24 values (i.e. the monthly temperatures in 1997-1998), we use the data upto the previous month for the fittings. We calculate MSE of one-step-ahead forecasts, two-step-ahead forecasts (by plug-in) for each of 7 cities.

	One-step MSE	Two-step MSE
VAR	$1.669_{(2.355)}$	$1.815_{(2.372)}$
RVAR	$1.677_{(2.324)}$	$1.829_{(2.398)}$
Segmentation	$1.381_{(1.888)}$	$1.543_{(1.874)}$

**Example 2.** 8 monthly US Industrial Production indices in 1947-1993 published by the US Federal Reserve.

8 indices: total index, manufacturing index, durable manufacturing, nondurable manufacturing, mining, utilities, products, materials.

Nonstationary trends: difference each series

– p.25

## **CCF of transformed differenced monthly US Industrial Indices**

- Visual examining CCF:  $\{1, 2, 3\}, \{4, 8\}$
- Permutation with max-CCF  $1 \le m \le 20$ :  $\{1, 3\}$
- Permutation with FDR

 $m = 20 \text{ and } \beta \in [10^{-6}, \ 0.01] \text{, or } m = 5 \text{ and } \beta \in [10^{-6}, \ 0.001]\text{:}$   $\{1,3\}$ 

- $m = 5 \text{ and } \beta = 0.005$ :  $\{1, 2, 3\}, \{4, 8\}$
- $m = 5 \text{ and } \beta = 0.01$ :  $\{1, 2, 3, 5, 6, 7\}$  and  $\{4, 8\}$ .

# Two recommended groupings: seven groups: $\{1,3\}$ five groups: $\{1,2,3\},\{4,8\}$

Methodology

## **Post-sample forecast**

Forecast 24 monthly indices in Jan 1992 – Dec 1993.

Using the segmentation:  $\{1,3\}$  and other six single element groups

Miss some small but significant cross correlations

	One-step MSE	Two-step MSE
VAR	$0.615_{(1.349)}$	$1.168_{(2.129)}$
RVAR	$0.606_{(1.293)}$	$1.159_{(2.285)}$
Segmentation	$0.588_{(1.341)}$	$1.154_{(2.312)}$

- Example 3. Weekly notified measles cases in 7 cities in England (i.e. London, Bristol, Liverpool, Manchester, Newcastle, Birmingham and Sheffield) in 1948-1965, before the advent of vaccination.
- All the 7 series show biennial cycles, which is the major driving force for the cross correlations among different cities.

n = 937, p = 7.

#### Weekly recorded cases of measles in 7 cities in England in 1948-1965

– p.30

## **CCF of weekly recorded cases of measles in 7 cities**

## **Transformation:** $\widehat{\mathbf{x}}_t = \widehat{\mathbf{B}} \mathbf{y}_t$

	(-4.898e4)	3.357e3	-3.315e04	-6.455e3	2.337e3	1.151e3	-1.047e3

Code:  $aek = a \times 10^{-k}$ 

#### **Transformed weekly recorded cases of measles in 7 cities**

– p.33

## **CCF of transformed weekly recorded cases of measles in 7 cities**

#### **CCF of prewhitened transformed weekly recorded cases of measles**

**Note.** When none of the component series are WN, the confidence bounds  $\pm 1.96/\sqrt{n}$  could be misleading.

## Segmentation assumption is invalid for this example!

(a) The maximum cross correlations, plotted in descending order, among each of the  $\binom{7}{2} = 21$  pairs component series of the transformed and prewhitened measles series. The maximization was taken over the lags between -20 to 20. (b) The ratios of two successive correlations in (a).

The segmentations determined by different numbers of connected pairs for the transformed measles series from 7 cities in England.

No. of connected pairs	No. of groups	Segmentation			
1	6	$\{4, 5\}, \{1\}, \{2\}, \{3\}, \{6\}, \{7\}$			
2	5	$\{1, 2\}, \{4, 5\}, \{3\}, \{6\}, \{7\}$			
3	4	$\{1, 2, 3\}, \{4, 5\}, \{6\}, \{7\}$			
4	3	{1, 2, 3, 7}, {4, 5}, {6}			
5	2	{1, 2, 3, 6, 7}, {4, 5}			
6	1	$\{1, \cdots, 7\}$			

## **Post-sample forecasting**

Forecast the notified measles cases in the last 14 weeks of the period for all 7 cities

Using the segmentation with four groups: {1, 2, 3}, {4, 5}, {6} and {7}

	One-step MSE	Two-step MSE
VAR	$503.408_{(1124.213)}$	$719.499_{(2249.986)}$
RVAR	$574.582_{(1432.217)}$	$846.141_{(2462.019)}$
Segmentation	$472.106_{(1088.17)}$	$654.843_{(1807.502)}$

**Example 4.** Daily impressions of 32 keywords for an air ticket booking website powered by Baidu (www.baidu.com) over 130 days.

n = 130, p = 32

Data have been coded to protect the confidentiality.

Advertisements are accessed by keywords search from a search engine.

Each display of an advertisement is counted as one impression.

Applying the proposed transformation with m = 10 (or  $1 \le m \le 15$ ), the transformed 32 time series are segmented into 31 groups with the only non-single-element group  $\{10, 13\}$ .

#### **Time series of 8 randomly selected daily impressions**

– p.40

## **CCF of 8 randomly selected daily impressions**

## CF of 8 prewhitened transformed daily impressions (6 randomly selected

Example 5. Daily sales of a clothing brand in 25 provinces in

China in 1 January 2008 – 16 December 2012.

 $n = 1812, \ p = 25$ 

Annual pattern: peak in February

Strong periodicity component with the period 7.

The 25 transformed series are segmented into 24 groups with  $\{15, 16\}$  as one group.

Permutation is performed using the max-CCF with  $14 \le m \le 30$ .

## **Time series of daily sales of a clothing brand in 8 provinces**

## **CCF of daily sales of a clothing brand in 8 provinces**

## **CCF of 8 transformed daily sales of a clothing brand**

## **CCF of 8 prewhitened transformed daily sales of a clothing brand**

## **Post-sample forecasting**

Forecast the daily sales for the last two weeks in each of the 25 provinces.

Segmentation: 24 groups with  $\{15, 16\}$  as one group

	One-step MSE	Two-step MSE
univariate AR	$0.208_{(1.255)}$	$0.194_{(1.250)}$
VAR	$0.295_{(2.830)}$	$0.301_{(2.930)}$
RVAR	$0.293_{(2.817)}$	$0.296_{(2.962)}$
Segmentation	$0.153_{(0.361)}$	$0.163_{(0.341)}$

Cross correlations between provinces are useful information. However they cannot be used via <u>direct VAR</u>!

#### **Asymptotic theory**

For  $p \times r$  matrices  $\mathbf{H}_1$  and  $\mathbf{H}_2$  and  $\mathbf{H}'_1\mathbf{H}_1 = \mathbf{H}'_2\mathbf{H}_2 = \mathbf{I}_r$ , let

$$D(\mathcal{M}(\mathbf{H}_1), \mathcal{M}(\mathbf{H}_2)) = \sqrt{1 - \frac{1}{r}} \operatorname{tr}(\mathbf{H}_1 \mathbf{H}_1' \mathbf{H}_2 \mathbf{H}_2').$$

Then  $D(\mathcal{M}(\mathbf{H}_1), \mathcal{M}(\mathbf{H}_2)) \in [0, 1]$ . It equals 0 iff  $\mathcal{M}(\mathbf{H}_1) = \mathcal{M}(\mathbf{H}_2)$ , and 1 iff  $\mathcal{M}(\mathbf{H}_1) \perp \mathcal{M}(\mathbf{H}_2)$ .

 $y_t$  is assumed to be weakly stationary and  $\alpha$ -mixing, i.e.

 $\alpha_k \equiv \sup_{i} \sup_{A \in \mathcal{F}^i_{-\infty}, B \in \mathcal{F}^\infty_{i+k}} |P(A \cap B) - P(A)P(B)| \to 0, \text{ as } k \to \infty,$ 

where  $\mathcal{F}_i^j = \sigma(\mathbf{y}_t : i \leq t \leq j)$ .

## p fixed

## C1. For some constant $\gamma > 2$ ,

$$\sup_{t} \max_{1 \le i \le p} E(|y_{i,t} - Ey_{i,t}|^{2\gamma}) < \infty.$$

C2.  $\sum_{k=1}^{\infty} \alpha_k^{1-2/\gamma} < \infty$ .

**Theorem 1.** Let conditions C1, C2 hold,  $\overline{\omega}$  be positive and p be fixed. Then there exists an  $\widehat{\mathbf{A}} = (\widehat{\mathbf{A}}_1, \cdots, \widehat{\mathbf{A}}_q)$  of which the columns are a permutation of the columns of  $\widehat{\Gamma}_y$ , such that

$$\max_{\mathbf{l} \le j \le q} D(\mathcal{M}(\widehat{\mathbf{A}}_j), \mathcal{M}(\mathbf{A}_j)) = O_p(n^{-1/2})$$

 $p = o(n^c)$  for some c > 0

C3. (Sparsity of  $\mathbf{A} = (a_{i,j})$ ) For some constant  $\iota \in [0, 1)$ ,

$$\max_{1\leq j\leq p}\sum_{i=1}^p|a_{i,j}|^\iota\leq s_1\qquad\text{and}\qquad\max_{1\leq i\leq p}\sum_{j=1}^p|a_{i,j}|^\iota\leq s_2,$$

where  $s_1$  and  $s_2$  are positive constants which may diverge together with p.

C4. For some positive constants l > 2 and  $\tau > 0$ ,

$$\sup_{t} \max_{1 \le i \le p} P(|y_{i,t} - \mu_i| > x) = O(x^{-2(l+\tau)}) \text{ as } x \to \infty.$$

C5.  $\alpha_k = O(k^{-l(l+\tau)/(2\tau)})$  as  $k \to \infty$ .

**Remark.** As  $\Sigma_y(k) = \mathbf{A}\Sigma_x(k)\mathbf{A}'$ , the sparsity of  $\mathbf{A}$  and the maximum block size of  $\Sigma_x(k)$  provide a measure for the sparsity of  $\Sigma_y(k)$ .

Let  $S_{\max}$  be the maximum block size in  $\Sigma_x(k)$ , and

$$\rho_j = \min_{\substack{1 \le i \le q \\ i \ne j}} \min |\lambda(\mathbf{W}_{x,i}) - \lambda(\mathbf{W}_{x,j})|, \qquad j = 1, \cdots, q,$$

 $\delta = s_1 s_2 \max_{k=1,...,k_0} \| \mathbf{\Sigma}_x(k) \|_{\infty}^{\iota}, \quad \kappa_1 = \min_{k=1,...,k_0} \| \mathbf{\Sigma}_x(k) \|_2, \quad \kappa_2 = \max_{k=1,...,k_0} \| \mathbf{\Sigma}_x(k) \|_2.$ 

**Thresholding CCVF**: Let  $\widehat{\Sigma}_y(k) = (\widehat{\sigma}_{i,j}(k))$  be CCVF. Define

$$\widetilde{\Sigma}_y(k) = \Big(\widehat{\sigma}_{i,j}(k)I\{|\widehat{\sigma}_{i,j}(k)| \ge u\}\Big), \qquad u = Mp^{2/l}n^{-1/2}$$

**Theorem 2**. Let conditions C3-C5 hold,  $\min_j \rho_j > 0$  and  $p = o(n^{l/4})$ . Then there exists an  $\widehat{\mathbf{A}} = (\widehat{\mathbf{A}}_1, \cdots, \widehat{\mathbf{A}}_q)$  of which the columns are a permutation of the columns of  $\widehat{\mathbf{\Gamma}}_y$ , such that

 $\max_{1 \le j \le q} \rho_j D(\mathcal{M}(\widehat{\mathbf{A}}_j), \mathcal{M}(\mathbf{A}_j))$ 

$$= \begin{cases} O_p \{ \kappa_2 (p^{4/l} n^{-1})^{(1-\iota)/2} S_{\max} \delta \}, & \kappa_1^{-1} (p^{4/l} n^{-1})^{(1-\iota)/2} S_{\max} \delta = O(1) \\ O_p \{ (p^{4/l} n^{-1})^{1-\iota} S_{\max}^2 \delta^2 \}, & \kappa_2 (p^{4/l} n^{-1})^{-(1-\iota)/2} S_{\max}^{-1} \delta^{-1} = O(1). \end{cases}$$

## Remarks

- (i) Theorem 2 gives the uniform convergence rate for  $\rho_j D(\mathcal{M}(\widehat{\mathbf{A}}_j), \mathcal{M}(\mathbf{A}_j))$ . The smaller  $\rho_j$  is, more difficult the estimation for  $\mathcal{M}(\mathbf{A}_j)$  is.
- (ii) The smaller  $\iota, s_1, s_2$  and  $S_{\max}$  are, more sparse  $\Sigma_y(k)$  is, and the faster the convergences are.
- (iii) Similar results can be obtained for the cases with  $\log p = o(n^c)$  by assuming the sub-Gaussianity for  $y_t$  and exponential decay rates for  $\alpha$ -mixing coefficients.

## Simulation

Let  $\mathbf{A} = (\mathbf{A}_1, \cdots, \mathbf{A}_q)$ ,  $\mathbf{A}_j$  is  $p \times p_j$ ,  $\sum_j p_j = p$ , and  $\widehat{\mathbf{A}} = (\widehat{\mathbf{A}}_1, \cdots, \widehat{\mathbf{A}}_{\widehat{q}}), \quad \widehat{\mathbf{A}}_j \text{ is } p \times \widehat{p}_j, \quad \sum_j \widehat{p}_j = p.$ Correct segmentation:  $\hat{q} = q$ ,  $\hat{p}_i = p_j$ , and  $D(\mathcal{M}(\mathbf{A}_j), \mathcal{M}(\widehat{\mathbf{A}}_j)) = \min_{1 \le i \le q} D(\mathcal{M}(\mathbf{A}_j), \mathcal{M}(\widehat{\mathbf{A}}_i)), \quad j = 1, \cdots, q.$ for  $\mathbf{H}_1'\mathbf{H}_1 = \mathbf{I}_{r_1}$  and  $\mathbf{H}_2'\mathbf{H}_2 = \mathbf{I}_{r_2}$ ,  $d(\mathcal{M}(\mathbf{H}_1), \mathcal{M}(\mathbf{H}_2)) = \left\{1 - \frac{1}{\min(r_1, r_2)} \operatorname{tr}(\mathbf{H}_1 \mathbf{H}_1' \mathbf{H}_2 \mathbf{H}_2')\right\}^{1/2}.$ 

Incomplete segmentation:  $\hat{q} < q$ , and each  $\mathcal{M}(\widehat{\mathbf{A}}_j)$  is an estimator for the linear space spanned by *one*, or *more than one*  $\mathbf{A}_i$ 

volatility

## No. of replications: 500 times for each setting.

Let  $\mathbf{A} = (a_{ij})$ ,  $a_{ij} \sim U(-3,3)$  independently.

**Example 6.** Let p = 6,  $\mathbf{y}_t = \mathbf{A}\mathbf{x}_t$ , and

$$x_{i,t} = \eta_{t+i-1}^{(1)}$$
 for  $i = 1, 2, 3, \ x_{j,t} = \eta_{t+j-4}^{(2)}$  for  $j = 4, 5, \ x_{6,t} = \eta_t^{(3)}$ .

where

$$\begin{split} \eta_t^{(1)} &= 0.5 \eta_{t-1}^{(1)} + 0.3 \eta_{t-2}^{(1)} + e_t^{(1)} - 0.9 e_{t-1}^{(1)} + 0.3 e_{t-2}^{(1)} + 1.2 e_{t-3}^{(1)} + 1.3 e_{t-4}^{(1)}, \\ \eta_t^{(2)} &= -0.4 \eta_{t-1}^{(2)} + 0.5 \eta_{t-2}^{(2)} + e_t^{(2)} + e_{t-1}^{(2)} - 0.8 e_{t-2}^{(2)} + 1.5 e_{t-3}^{(2)}, \\ \eta_t^{(3)} &= 0.9 \eta_{t-1}^{(3)} + e_t^{(3)}, \end{split}$$

and  $e_t^{(1)}, e_t^{(2)}, e_t^{(3)}$  are indep N(0, 1). Thus

q = 3, i.e. 3 segmented subseries with 3, 2, 1 elements.

## **Relative frequencies of correct and incomplete segmentations**

n	100	200	300	400	500	1000	1500	2000	2500	3000
Correct	.350	.564	.660	.712	.800	.896	.906	.920	.932	.945

Boxplots of  $\frac{1}{3} \sum_{1 \le i \le 3} D(\mathcal{M}(\mathbf{A}_i), \mathcal{M}(\widehat{\mathbf{A}}_i))$  (with correct segmentations only)

## **CCF** of $y_t$ (one instance)

## **CCF of** $\widehat{\mathbf{x}}_t$ (one instance)

Segmentation:  $\{1, 4, 6\}, \{2, 5\}, \{3\}$
**Example 7.** Let 
$$p = 20, q = 5, (p_1, \dots, p_5) = (6, 5, 4, 3, 2)$$

 $\mathbf{x}_t$  is defined similarly as in Example 6.

#### Relative frequencies of correct and incomplete segmentations

n	400	500	1000	1500	2000	2500	3000
Correct	0.058	0.118	0.492	0.726	0.862	0.902	0.940
Incomplete	0.516	0.672	0.460	0.258	0.130	0.096	0.060

Boxplots of  $\frac{1}{5} \sum_{1 \le i \le 5} D(\mathcal{M}(\mathbf{A}_i), \mathcal{M}(\widehat{\mathbf{A}}_i))$  (with correct segmentations only)

Segmenting multiple volatility processes Let  $\mathcal{F}_t = \sigma(\mathbf{y}_t, \mathbf{y}_{t-1}, \cdots)$ ,

$$E(\mathbf{y}_t | \mathcal{F}_{t-1}) = \mathbf{0}, \quad Var(\mathbf{y}_t | \mathcal{F}_{t-1}) = \mathbf{\Sigma}_y(t).$$

Assumption:  $\mathbf{y}_t = \mathbf{A}\mathbf{x}_t$ ,  $\operatorname{Var}(\mathbf{x}_t | \mathcal{F}_{t-1}) = \operatorname{diag}(\boldsymbol{\Sigma}_1(t), \cdots, \boldsymbol{\Sigma}_q(t))$ .

Let  $Var(\mathbf{y}_t) = Var(\mathbf{x}_t) = \mathbf{I}_p$ , then A is orthogonal.

Let  $\mathcal{B}_{t-1}$  be a  $\pi$ -class and  $\sigma(\mathcal{B}_{t-1}) = \mathcal{F}_{t-1}$ . put

$$\mathbf{W}_y = \sum_{B \in \mathcal{B}_{t-1}} [E\{\mathbf{y}_t \mathbf{y}'_t I(B)\}]^2, \quad \mathbf{W}_x = \sum_{B \in \mathcal{B}_{t-1}} [E\{\mathbf{x}_t \mathbf{x}'_t I(B)\}]^2.$$

For any  $B \in \mathcal{B}_{t-1}$ ,

 $E\{\mathbf{x}_t\mathbf{x}_t'I(B)\} = E[I(B)E\{\mathbf{x}_t\mathbf{x}_t'|\mathcal{F}_{t-1}\}] = E[I(B)\operatorname{diag}(\mathbf{\Sigma}_1(t),\cdots,\mathbf{\Sigma}_q(t))]$ 

is a block diagonal matrix, so is  $\mathbf{W}_x$ .

Since

$$\mathbf{W}_y = \mathbf{A}\mathbf{W}_x\mathbf{A}',$$

the proposed method continues to apply.

In practice we estimate  $W_y$  by

$$\widehat{\mathbf{W}}_{y} = \sum_{B \in \mathcal{B}} \sum_{k=1}^{k_{0}} \left( \frac{1}{n-k} \sum_{t=k+1}^{n} \mathbf{y}_{t} \mathbf{y}_{t}^{\prime} I(\mathbf{y}_{t-k} \in B) \right)^{2},$$

where  $\mathcal{B}$  may consist of  $\{\mathbf{u} \in R^p : \|\mathbf{u}\| \leq \|\mathbf{y}_t\|\}$  for  $t = 1, \cdots, n$ .

**Example 8**. Consider the daily returns in 2 Jan 2002 – 10 July 2008 of six stocks: *Bank of America, Dell, JPMorgan, FedEx, McDonald and American International Group*.

n = 1642, p = 6

$\widehat{\mathbf{B}} =$	(-0.227)	-0.093	0.031	0.550	0.348	-0.041

	0.144	-0.012	-0.582	0.131	0.098	-0.028 /

Segmentation for transformed series:

CUC of Fan, Wang & Y (2008)

# **Daily returns of 6 stocks**

### **CCF of squared returns**

## **CCF** of residuals from fitted GARCH(1,1) for each return series

## **CCF of squared transformed returns**

#### **CCF of residuals from transformed return series**

# Conclusions

- A new version of PCA for time series: finding a latent segmentation via a contemporaneous linear transformation
- When the segmentation does not exist, provide effective approximations by ignoring negligible, though significant, correlations
- Why works?  $\mathbf{W}_y = \sum_k \mathbf{\Sigma}_y(k) \mathbf{\Sigma}_y(k)' = \mathbf{A} \mathbf{W}_x \mathbf{A}'$ ,

$$\operatorname{tr}(\mathbf{W}_y) = \sum_k \sum_{i,j=1}^p \rho_{ij}^y(k)^2 = \operatorname{tr}(\mathbf{W}_x) = \sum_k \sum_{i,j=1}^p \rho_{ij}^x(k)^2 = \sum_k \sum_i \rho_{ii}^x(k)^2$$

provided all components of  $\mathbf{x}_t$  are uncorrelated across all time lags

Components of  $x_t$  are more predictable, due to stronger ACF!

• When latend segmentation does not exist, use  $\mathbf{z}_t = \Gamma'_u \mathbf{y}_t$ ,

$$\mathbf{W}_y = \sum_k \boldsymbol{\Sigma}_y(k) \boldsymbol{\Sigma}_y(k)' = \boldsymbol{\Gamma}_y \mathbf{D} \boldsymbol{\Gamma}'_y.$$

Hence  $\Sigma_z(k) = \Gamma_y' \Sigma_y(k) \Gamma_y$ , and therefore

$$\mathbf{W}_z = \sum_k \boldsymbol{\Sigma}_z(k) \boldsymbol{\Sigma}_z(k)' = \boldsymbol{\Gamma}'_y \mathbf{W}_y \boldsymbol{\Gamma}_y = \mathbf{D},$$

i.e.  $\mathbf{W}_z$  is a diagonal matrix.

- Note.  $\Sigma_z(k)$  are unlikely to be diagonal, though the off-diagonal elements tend to be small.
- Improve the test for vector white noise: Chang, Yao and Zhou (2015).
