Applications of Peter Hall's martingale limit theory to estimating and testing high dimensional covariance matrices

Danning Li, Lingzhou Xue and Hui Zou

Jilin University, Pennsylvania State University and University of Minnesota

Abstract: Martingale limit theory is increasingly important in modern probability theory and mathematical statistics. In this article, we give a selected overview of Peter Hall's contributions to both the theoretical foundations and the wide applicability of martingales. We highlight his celebrated coauthored book, Hall and Heyde (1980) and his ground-breaking paper, Hall (1984). To illustrate the power of his martingale limit theory, we present two contemporary applications to estimating and testing high dimensional covariance matrices. In the first, we use the martingale central limit theorem in Hall and Heyde (1980) to obtain the simultaneous risk optimality and consistency of Stein's unbiased risk estimation (SURE) information criterion for large covariance matrix estimation. In the second application, we use the central limit theorem for degenerate U-statistics in Hall (1984) to establish the consistent asymptotic size and power against more general alternatives when testing high-dimensional covariance matrices.

Key words and phrases: Large covariance matrix, Martingale limit theory, Degenerate U-statistics, Stein's unbiased risk estimation, Hypothesis testing.

1. Introduction

The concept of *martingale* was first introduced by Paul Levy in probability theory, and its name was introduced later by Jean Ville, in 1939. The early development of martingale theory includes Levy's martingale characterization, Bernstein's inequality for weakly dependent random variables, and Doob's martingale convergence theorems. The interplay of theory and applications is evident in the history of probability and mathematical statistics. Statisticians have employed martingales as a technical tool in a wide range of applications since the 1970s. As a result, asymptotic properties of martingales were of increasing importance in studying complex probabilistic behaviors. Peter Hall became a world leader in the theory of martingales when he was working on his master and doctoral theses at Australian National University and Oxford University, advised by Chris Heyde and John Kingman respectively. He was introduced as "Mr Martingale" when he visited the University of Cambridge in the mid-1970s (Delaigle and Speed (2016)). He made fundamental contributions to both the theoretical foundations and the wide applicability of martingales.

We first give a selected overview of Peter Hall's contributions to martingale limit theory. His main research interests focus on the martingale central limit theorems and invariance principles (Brown (1971); McLeish

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

(1974)), which are the heart of the book by Hall and Heyde (1980). Hall (1977) derived the general martingale central limit theorems and invariance principles under relaxed conditions. Hall (1978) generalized Bernstein's discovery of the convergence of moments in the central limit theorem to the martingale case, and proved the convergence of moments in martingale central limit theorems. Hall and Heyde (1976) used the Skorokhod representation to obtain a unified approach to the law of the iterated logarithm for martingales, and Hall (1979a) worked out the powerful Skorokhod representation method to prove Martingale invariance principles under quite general conditions. Hall and Heyde (1981) obtained the nonuniform estimate of the rate of convergence in the martingale central limit theorem, which provides a martinagle analogue of Feller's generalization of the Berry-Esseen theorem.

Hall and Heyde (1980) is one of the most important reference books in martingales. It provides a comprehensive overview of the state-of-the-art martingale limit theory and wide applications to illustrate the power of martingale methods. The book bridged the gap between martingale theory and applications, and it has had a broad, significant and long-lasting impact on numerous areas of probability theory, mathematical statistics, and econometrics. In another ground-breaking paper, Hall (1984) used martingale theory to obtain a central limit theorem for degenerate U-statistics with applications

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

to multivariate nonparametric density estimators. Consider the degenerate U-statistic $U_n = \sum\sum_{1\le i<j\le n} H_n(X_i, X_j)$ where $X_1, \cdots, X_n$ are independent and identically distributed random observations, and $E[H_n(X_1, X_2)|X_1] = 0$ almost surely. Hall (1984) assumed more practicable conditions to derive the central limit theorem of U_n. Let $G_n(x, y) = E[H_n(X_1, x)H_n(X_1, y)]$. More specifically, given that H_n is symmetric, $E[H_n^2(X_1, X_2)] < \infty$, and

$$\lim_{n\to\infty} \frac{E[G_n^2(X_1, X_2)] + \frac{1}{n}E[H_n^4(X_1, X_2)]}{\{E[H_n^2(X_1, X_2)]\}^2} = 0,$$

Hall (1984) proved that U_n is asymptotically normally distributed with zero mean and covariance matrix $\frac{1}{2}n^2E[H_n^2(X_1, X_2)]$. Because of Hall and Heyde (1980) and Hall (1984), theoretical progress in martingales has led to a number of important research topics: weak convergence of U-statistics and empirical processes (Loynes (1978); Hall (1979b)), weak convergence of log-likelihood-ratio processes (Hall and Loynes (1977)), nonparametric function estimation and modeling (Hall (1984); Hardle et al. (1988); Hall et al. (1992); Racine and Li (2004)), sliced inverse regression (Hsing and Carroll (1992); Hall and Li (1993)), empirical likelihood estimation (Donald et al. (2003)), unit root tests in time series regression (Phillips and Perron (1988); Elliott et al. (1996)), structural change estimation in econometric models

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

(Andrews (1993); Bai and Perron (1998)), autocorrelation matrix estimation (Andrews (1991)), and many others. In recent years, the martingale limit theory in Hall and Heyde (1980) and Hall (1984) has received considerable attention in the development of high-dimensional statistical inference such as high-dimensional mean tests (Chen and Qin (2010); Wang et al. (2015)), high-dimensional covariance tests (Schott (2007); Lan et al. (2015); Li and Xue (2015); He and Chen (2016)), and inference on conditional dependence (Wang et al. (2015)), among others.

In the rest of this paper, we present applications of Hall and Heyde (1980) and Hall (1984) to estimating and to testing high dimensional covariance matrices. Section 2 applies the martingale central limit theorem to obtain consistency for Stein's unbiased risk estimation (SURE) information criteria (Stein (1981); Efron (1986, 2004)) for large covariance matrix estimation. Section 3 applies the central limit theorem for degenerate U-statistics in Hall (1984) to establish the consistent asymptotic size and power for a new test statistic against more general alternatives when testing high-dimensional covariance matrices. Section 4 provides numerical studies to demonstrate the finite-sample performance. The complete proofs of main results are included in a separate supplementary file.

2. Application to The SURE Information Criterion

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

Let $X_1, \cdots, X_n$ be independent and identically distributed p-dimensional Gaussian observations with mean vector μ and covariance matrix $\Sigma_{p\times p} = \left(\sigma_{ij}\right)_{p\times p}$. We assume that $p \geq n$ and p is of a nearly exponential order of n (i.e., $\log(p) = o(n)$). The problem of estimating Σ is important to various multivariate statistical methods and theory. Let $\tilde{\Sigma}^s = \left(\tilde{\sigma}^s_{ij}\right)_{p\times p}$ be the sample covariance matrix. It is well-known that $\tilde{\Sigma}^s$ performs poorly when estimating Σ in high dimensions. Several regularized estimators of large covariance matrices have been proposed, including banding (Wu and Pourahmadi (2003); Bickel and Levina (2008a); Fan et al. (2016)), tapering (Furrer and Bengtsson (2007); Cai et al. (2010); Xue and Zou (2014)), and thresholding (Bickel and Levina (2008b); Rothman et al. (2009); Cai and Liu (2011); Xue et al. (2012)). The minimax optimality was established for large covariance matrix estimation (Cai et al. (2010); Cai and Zhou (2012); Xue and Zou (2013)).

Little is known about the model selection criterion when estimating large covariance matrices. Stein's unbiased risk estimation (SURE) information criterion (Stein (1981)) has shown appealing performances in adaptive wavelet thresholding (Donoho and Johnstone (1995)) and sparse linear regression (Efron et al. (2004); Zou et al. (2007)). Based on martingale central limit theorems in Hall and Heyde (1980), we attempt to obtain model

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

selection consistency of SURE information criterion for large covariance matrix estimation. To facilitate discussion, we focus on the estimation of large bandable covariance matrices, which have natural applications for modeling temporal and spatial dependence. Following Bickel and Levina (2008a) and Cai et al. (2010), we assume that Σ is in

$$\mathcal{G}_\alpha = \{\Sigma : \ |\sigma_{ij}| \le M_1 |i-j|^{-(\alpha+1)}, \forall\, i \ne j, \ \text{and}\, \lambda_{\max}(\Sigma) \le M_0\}, \qquad (2.1)$$

where $\lambda_{\max}(\Sigma)$ is the largest eigenvalue of matrix Σ, and α, M_0, and M_1 are positive constants. The constant α controls the decay rate of the off-diagonal elements of Σ. Without loss of generality, we assume $\sigma_{ii} = 1$ for $1 \le i \le p$ in this section.

To estimate Σ in $\mathcal{G}_\alpha$, we consider the banded covariance matrix

$$\hat{\Sigma}^{(\tau)} = \left(\hat{\sigma}_{ij}^{(\tau)}\right)_{1 \le i,j \le p}$$

where $\hat{\sigma}_{ij}^{(\tau)} = \omega_{ij}^{(\tau)} \tilde{\sigma}_{ij}$ and $\omega_{ij}^{(\tau)}$ is the banding weight satisfying: (i) $\omega_{ij}^{(\tau)} = 1$ for $|i-j| < \tau$; (ii) $\omega_{ij}^{(\tau)} = 0$ for $|i-j| \ge \tau$. We need to properly choose the banding parameter τ in practice.

We introduce the SURE information criterion to select the banding parameter. Let $R(\tau) = \mathbb{E}\|\hat{\Sigma}^{(\tau)} - \Sigma\|_F^2$ be the Frobenius risk of $\hat{\Sigma}^{(\tau)}$. Here

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

$R(\tau)$ satisfies the Stein's identity

$$R(\tau) = \mathbb{E}\|\hat{\Sigma}^{(\tau)} - \tilde{\Sigma}^s\|_F^2 - \sum_{i,j} \mathrm{var}(\tilde{\sigma}_{ij}^s) + 2\sum_{i,j} \mathrm{cov}(\hat{\sigma}_{ij}^{(\tau)}, \tilde{\sigma}_{ij}^s), \tag{2.2}$$

where we used the fact that $\tilde{\Sigma}^s$ is an unbiased estimate for Σ. The third term on the right-hand side is referred to as the covariance penalty (Efron (2004)). By definition, we obtain that $\mathrm{cov}(\hat{\sigma}_{ij}^{(\tau)}, \tilde{\sigma}_{ij}^s) = \frac{n-1}{n}\omega_{ij}^{(\tau)}\mathrm{var}(\tilde{\sigma}_{ij}^s)$. Let $\widehat{\mathrm{var}}(\tilde{\sigma}_{ij}^s)$ be an unbiased estimator of $\mathrm{var}(\tilde{\sigma}_{ij}^s)$. Then, we derive Stein's unbiased risk estimator of $R(\tau)$ as

$$\mathrm{SURE}(\tau) \;=\; \|\hat{\Sigma}^{(\tau)} - \tilde{\Sigma}^s\|_F^2 - \sum_{i,j} \widehat{\mathrm{var}}(\tilde{\sigma}_{ij}^s) + 2\frac{n-1}{n}\sum_{i,j} \omega_{ij}^{(\tau)}\widehat{\mathrm{var}}(\tilde{\sigma}_{ij}^s) \tag{2.3}$$

We find that $\mathbb{E}[\mathrm{SURE}(\tau)] = R(\tau)$. Following Yi and Zou (2013) and Li and Zou (2016), one sees that $\mathrm{SURE}(\tau)$ has an explicit expression as

$$\mathrm{SURE}(\tau) \;=\; \sum_{1\le i,j\le p} (\frac{n}{n-1} - \omega_{ij}^{(\tau)})^2\tilde{\sigma}_{ij}^2 + \sum_{1\le i,j\le p} (2\omega_{ij}^{(\tau)} - \frac{n}{n-1})(a_n\tilde{\sigma}_{ij}^2 + b_n\tilde{\sigma}_{ii}\tilde{\sigma}_{jj}),$$

with $a_n = \frac{n(n-3)}{(n-1)(n-2)(n+1)}$ and $b_n = \frac{n}{(n+1)(n-2)}$.

Now, we can select the banding parameter by the SURE tuning

$$\hat{\tau}_n = \arg\min_{\tau}\ \mathrm{SURE}(\tau). \tag{2.4}$$

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

Efron (1986, 2004) showed that SURE is equivalent to AIC for regression models with an additive homoscedastic Gaussian noise. It is also known that AIC yields an asymptotic minimax optimal estimator (Yang (2005)). It was expected that SURE(τ) might have the fundamental properties of AIC (Shao (1997); Yang (2005)) and result in a minimax optimal banded covariance matrix estimator. Li and Zou (2016) proved that by minimizing SURE(τ) over all possible banded estimators, we obtain the minimax optimal rate of convergence and the resulting estimator $\hat{\Sigma}^{(\hat{\tau}_n)}$ is comparable to the oracle estimator $\hat{\Sigma}^{(k_0)}$ given the true banding parameter k_0,

$$\sup_{\Sigma \in \mathcal{G}_\alpha} \mathbb{E}\|\hat{\Sigma}^{(\hat{\tau}_n)} - \Sigma\|_F^2 \asymp \sup_{\Sigma \in \mathcal{G}_\alpha} \mathbb{E}\|\hat{\Sigma}^{(k_0)} - \Sigma\|_F^2.$$

Thus, we can regard SURE(τ) as the analogue of AIC for large bandable covariance matrix estimation. Here we study the bandwidth selection property of SURE tuning. In applications, the SURE information criterion would be more appealing if it was consistent in identifying the true bandwidth. In traditional linear regression, AIC is risk optimal, and BIC is known for its selection consistency property (Shao (1997); Yang (2005)). Recently, certain AIC-type criteria have been shown to achieve the consistency property under a high-dimensional setting. For instance, Fujikoshi et al. (2014) and

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

Yanagihara et al. (2015) established the consistency of AIC-type criteria in high-dimensional multivariate linear regression, and Bai et al. (2015) established the consistency of AIC-type criteria in high-dimensional principal component analysis. Here we use the martingale central limit theorem in Hall and Heyde (1980) to prove that when the true covariance matrix is banded, by minimizing SURE(τ) we select the true bandwidth with probability one.

Theorem 1. *Let $\Sigma_0 \in \mathcal{G}_\alpha$ be the true banded matrix with bandwidth k_0, where $\sigma_{ij} = 0$ if $|i-j| \geq k_0$. In $\frac{1}{p} \min_{h \leq k_0 - 1} \sum_{|i-j|=h} \sigma_{ij}^2 \gg \log n/n$, then, with probability one, SURE achieves the bandwidth selection consistency that $\hat{\tau}_n = k_0$.*

3. Application to Testing the Covariance Structure

Let $X_1, \cdots, X_n$ be independent and identically distributed p-dimensional Gaussian observations with mean vector μ and covariance matrix Σ. We assume that $p \gg n$ and $\lambda_{max}(\Sigma) < M_0$ for some constant M_0. Testing the covariance structure in Σ is of importance in a wide range of research fields. In Section 3, we consider testing the hypothesis that Σ is banded with some given bandwidth $k_0 \geq 1$,

$$\mathbf{H}_0 : \sigma_{ij} = 0, \quad \forall (i,j) \text{ such that } |i-j| \geq k_0. \tag{3.1}$$

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

When $k_0 = 1$, $\mathbf{H}_0$ corresponds to testing the mutual independence of Gaussian random variables. In the literature, $\mathbf{H}_0$ has been considered in Cai and Jiang (2011), Qiu and Chen (2012, 2015), among others. We introduce two parameter spaces for Σ:

$$\begin{aligned}\mathcal{G}_1 &= \left\{\Sigma = (\sigma_{ij})_{p\times p}:\ \sigma_{ii} = \sigma_{ji} \text{ and } \max_{|i-j|\geq k_0} |\sigma_{ij}| > C\sqrt{\frac{\log p}{n}}\right\};\\ \mathcal{G}_2 &= \left\{\Sigma = (\sigma_{ij})_{p\times p}:\ \sigma_{ii} = \sigma_{ji} \text{ and } \frac{n}{p}\sum_{|i-j|\geq k_0} \sigma_{ij}^2 \gg \log p\right\}.\end{aligned}$$

In this $\mathcal{G}_1$ represents the parameter space in which the covariance has a few relatively large entries with $|i-j| \geq k_0$, and $\mathcal{G}_2$ denotes the parameter space in which the covariance contains a lot of small nonzero entries with $|i-j| \geq k_0$. In current literature, extreme-value type statistics test against the sparse alternative $\mathcal{G}_1$ (Cai and Jiang (2011)), and sum-of-squares type statistics test against the dense alternative $\mathcal{G}_2$ (Qiu and Chen (2012, 2015)). As we do not have the prior knowledge of the sparse or dense alternative in practice, it is important to effectively test against general alternatives. Here we are interested in testing procedure that boosts power against the more general alternative that

$$\mathbf{H}_1 : \Sigma \in \mathcal{G}_1 \cup \mathcal{G}_2. \tag{3.2}$$

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

Let $\Gamma = (\rho_{ij})_{p\times p}$ be the corresponding correlation matrix, and $\tilde{\Gamma} = (\tilde{\rho}_{ij})$ its sample estimate where $\bar{x}_k = (1/n)\sum_{i=1}^n x_{ik}$ and

$$\tilde{\rho}_{ij} = \frac{(x_i - \bar{x}_i)^T(x_j - \bar{x}_j)}{\|x_i - \bar{x}_i\| \cdot \|x_j - \bar{x}_j\|}, \quad 1 \le i, j \le p \tag{3.3}$$

Cai and Jiang (2011) proposed the maximum test statistic

$$L_n = \max_{|i-j|\ge k_0} |\tilde{\rho}_{ij}|, \tag{3.4}$$

Let $\Gamma_{p,\delta} = \{1 \le i \le p;\ |\rho_{ij}| > 1 - \delta \text{ for some } 1 \le j \le p \text{ with } j \ne i\}$ for any $0 < \delta < 1$. When $p \to \infty$ with $\log p = o(n^{1/3})$ and $|\Gamma_{p,\delta}| = o(p)$, Cai and Jiang (2011) proved that $nL_n^2 - 4\log p + \log\log p$ converges weakly to an extreme distribution of type I with the distribution function $F(y) = e^{-\frac{1}{\sqrt{8\pi}}e^{-y/2}}$, $\forall y \in \mathbb{R}$ under $\mathbf{H}_0$. However, Hall (1979c) and Li and Xue (2015) point out that the extreme-value form statistic L_n may suffer from low power against dense alternatives with $\Sigma \in \mathcal{G}_2$.

To boost the power of L_n against $\mathbf{H}_1$, we introduce a quadratic form statistic. To this end, take $Z_i = \frac{1}{\sqrt{i(i+1)}}(X_1 + \ldots + X_i) - \frac{i}{\sqrt{i(i+1)}}X_{i+1}$ for $1 \le i \le n-1$ and $Z_n = \frac{1}{\sqrt{n}}\sum_{i=1}^n X_i$. Note that $Z_1, \cdots, Z_{n-1}$ are *i.i.d.* $N_p(0, \Sigma)$ random vectors. Using Theorem 3.1.2 from Murihead (1983), $\tilde{\Sigma} = \frac{1}{n}\sum_{k=1}^n (X_k - \bar{X})(X_k - \bar{X})^T$ is equal to $\hat{\Sigma} = \left(\hat{\sigma}_{ij}\right)_{1\le i,j\le p} = \frac{1}{n}\sum_{k=1}^{n-1} Z_k Z_k^T$.

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

Now we define the quadratic form statistic as follows:

$$Q_n^2 = \frac{S_n^2(k_0)}{S}, \tag{3.5}$$

where

$$\begin{aligned} S_n^2(k_0) &= \sum_{1\le i,j\le p} \omega_{ij}^{(k_0)} \{\hat{\sigma}_{ij}^2 - \sum_{m=1}^{n-1} \frac{(z_{mi}z_{mj})^2}{n^2}\}, \\ \text{and} \quad S^2 &= \sum_{1\le l<m\le n} \{\frac{1}{n^2} \sum_{1\le i,j\le p} 2\omega_{ij}^{(k_0)} z_{mi}z_{mj}z_{li}z_{lj}\}^2. \end{aligned} \tag{3.6}$$

We follow Hall (1984) to derive the central limit theorem for $S_n^2(k_0)$. Let $H_n(Z_m, Z_l) = \frac{1}{n^2} \sum_{1\le i,j\le p} 2\omega_{ij}^{(k_0)}(z_{mi}z_{mj} - \sigma_{ij})(z_{li}z_{lj} - \sigma_{ij})$ and

$$Y_m = \frac{2(n-2)}{n^2} \sum_{1\le i,j\le p} \omega_{ij}^{(k_0)} \sigma_{ij}(z_{mi}z_{mj} - \sigma_{ij}),$$

where $\omega_{ij}^{(k_0)}$s are the same banding weights defined in Section 2. We can rewrite the difference $S_n^2(k_0) - ES_n^2(k_0)$ as

$$\begin{aligned} S_n^2(k_0) - ES_n^2(k_0) &= \sum_{1\le i,j\le p} \omega_{ij}^{(k_0)} (\hat{\sigma}_{ij}^2 - \sum_{m=1}^{n-1} \frac{(z_{mi}z_{mj})^2}{n^2} - \frac{n(n-1)}{n^2}\sigma_{ij}^2) \\ &= \sum_{m=2}^{n-1} \sum_{l=1}^{m-1} H_n(Z_m, Z_l) + \sum_{m=2}^{n-1} Y_m, \end{aligned} \tag{3.7}$$

where we used the fact that $E\hat{\Sigma} = \Sigma$. Under $\mathbf{H}_0$, $Y_m = 0$ and $ES_n^2(k_0) = 0$. Then as shown in (3.7), $S_n^2(k_0) - ES_n^2(k_0)$ is a degenerate U statistic of the

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

form of U_n in Hall (1984).

We follow Theorem 1 of Hall (1984) to show a central limit theorem for $S_n^2(k_0)$.

Theorem 2. *Let* $\mathrm{Var}_n(k_0) = \frac{n(n-1)}{2} E(H_n(Z_1, Z_2)^2)$. *Under* $\mathbf{H}_0$,

$$\mathrm{Var}_n(k_0)^{-\frac{1}{2}}(S_n^2(k_0) - ES_n^2(k_0)) \to N(0,1)$$

in distribution as $n \to \infty$. *Further,*

$$\sup_t |P(\frac{S_n^2(k_0) - ES_n^2(k_0)}{\sqrt{\mathrm{Var}_n(k_0)}} \le t) - \Phi(t)| \le Cn^{-1/5}.$$

As well, we have the convergency of S^2 in probability to $\mathrm{Var}_n(k_0)$.

Theorem 3. *Under* $\mathbf{H}_0$, $\frac{S^2}{\mathrm{Var}_n(k_0)} \to 1$ *in probability as* $n \to \infty$.

Combining Theorems 3–4 and Slutsky's theorem, we obtain a central limit theorem for Q_n^2.

Theorem 4. *Under* $\mathbf{H}_0$, Q_n^2 *converges weakly to* $N(0,1)$ *as* $n \to \infty$.

Now, we combine the strengths of both Q_n^2 and L_n and propose a new testing procedure:

$$TS = I_{\{Q_n^2 + (nL_n^2 - 4\log p + \log\log p) \ge c_\alpha\}}$$

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

where the threshold c_α is defined as the α upper quantile of the convolution distribution $\Phi \star F$. Here $TS = 1$ leads to the rejection of $\mathbf{H}_0$. In what follows, we provide the theoretical guarantee of its asymptotic size and power. To this end, we define the marginal distribution functions of Q_n and L_n as

$$P_{Q_n}(z) = P\big(Q_n^2 \le z\big),\ P_{L_n}(y) = P\big(nL_n^2 - 4\log p + \log\log p \le y\big),$$

as well as their joint distribution function as

$$P_{Q_n,L_n}(z,y) = P\big(\{Q_n^2 \le z\} \cap \{nL_n^2 - 4\log p + \log\log p \ge y\}\big).$$

We derive the explicit joint limiting law of Q_n and L_n, that shares the spirit of Li and Xue (2015).

Theorem 5. *If $|\Gamma_{p,\delta}| = o(p)$ for $\delta \in (0,1)$ and $p \to \infty$ with $\log p = o(n^{1/5})$, then, under $\mathbf{H}_0$, for any z and y we have*

$$P_{Q_n,L_n}(z,y) \to \Phi(z)\left(1 - e^{\frac{-1}{\sqrt{8\pi}}e^{\frac{-y}{2}}}\right). \tag{3.8}$$

Let $P_{\mathbf{H}_0}(\cdot)$ be the probability given the null hypothesis $\mathbf{H}_0$, and $P_{\mathbf{H}_1}(\cdot)$ be the probability given the alternative hypothesis $\mathbf{H}_1$. $P_{\mathbf{H}_0}(TS = 1)$ is the conditional probability of rejecting $\mathbf{H}_0$ given that $\mathbf{H}_0$ is true, and

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

$P_{\mathbf{H}_1}(TS = 1)$ is the conditional probability of correctly rejecting $\mathbf{H}_0$. In the sequel, we prove that TS does control the significance level and also achieves consistent power.

Theorem 6. *Under the conditions of Theorem 5, we have*

$$P_{\mathbf{H}_0}(TS = 1) \to \alpha \quad as\ n \to \infty.$$

Otherwise, if $p/n \to \infty$ *and* $\Sigma \in \mathcal{G}_1 \cup \mathcal{G}_2$, *we have*

$$\inf_{\Sigma \in \mathcal{G}_1 \cup \mathcal{G}_2} P_{\mathbf{H}_1}(TS = 1) \to 1 \quad as\ n \to \infty.$$

4. Numerical Properties

In this section, we demonstrate the numerical performance of our proposed SURE information criterion and our proposed new testing procedure. We consider three different models to simulate the independent observations $X_1, \cdots, X_n$ that are $N_p(0, \Sigma)$, and $\Sigma = (\sigma_{ij})_{p\times p}$ specifies the covariance structure:

- `Model 1.` $\sigma_{ij} = I(i = j) + \frac{1}{4} I(|i - j| \le 4)$ for $1 \le i, j \le p$.
- `Model 2.` $\sigma_{ij} = I(i = j) + \frac{1}{4} I(|i - j| \le 4) + 0.45 I(i = 7, j = 1) + 0.45 I(i = 1, j = 7)$ for $1 \le i, j \le p$.

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

- `Model 3.` $\sigma_{ij} = I(i=j) + \frac{1}{4}I(|i-j| \le 4) + 2.5\sqrt{\frac{logp}{n}}I(|i-j| \ge 5)$ for $1 \le i, j \le p$.

Model 1 specifies a banded covariance matrix with bandwidth 5 to evaluate the proposed SURE information criterion. Model 1 mimics the null hypothesis $\mathbf{H}_0$ in Section 3 to examine the size. Model 2 corresponds to a covariance matrix in $\mathcal{G}_1$ with only two relatively large entries (i.e., σ_{17} and σ_{71}) with $|i-j| > 4$. Model 3 corresponds to a covariance matrix in $\mathcal{G}_2$ with many small disturbances. For each simulation model, we let $n = 200$ and $p = 50, 100, 200, 400, 800$, and generated 1000 independent repetitions.

To check the finite-sample performance of our proposed SURE selection in Model 1, we report the frequencies of selecting the corresponding bandwidth among 1000 repetitions in Table 1. Our proposed SURE achieves the desired selection consistency, which is consistent with Theorem 1 of Section 2.

Table 1: Selection performance of SURE information criterion in Model 1.

Selected bandwidth	4	5	6
$p = 200$	0/1000	1000/1000	0/1000
$p = 400$	0/1000	1000/1000	0/1000
$p = 800$	0/1000	1000/1000	0/1000

We examine the proposed new testing procedure together with the maximum form test statistic L_n in (3.4) and the quadratic form test statistic

Statistica Sinica: Preprint
doi:10.5705/ss.202017.0060

Q_n^2 in (3.5). Simulation results are summarized in Tables 2-4. As shown in Table 2, all three testing procedures achieve the reasonably good size in Model 1. As to power, L_n clearly suffers from low power against dense alternatives, and Q_n^2 suffers from low power against sparse alternatives. However, TS retains good power against the sparse alternative in Model 2 and the dense alternative in Model 3.

Table 2: Performance of different testing procedures in Model 1.

p	Q_n^2	L_n	TS
50	0.0476	0.0266	0.034
100	0.044	0.029	0.0348
200	0.0408	0.026	0.0272
400	0.045	0.0226	0.0234
800	0.0446	0.0218	0.0204

Table 3: Performance of different testing procedures in Model 2.

p	Q_n^2	L_n	TS
50	0.1416	0.996	0.996
100	0.078	0.99	0.9902
200	0.0546	0.9788	0.9756
400	0.053	0.953	0.9502
800	0.0514	0.914	0.8504

Supplementary Materials

In the online supplement, we provide the complete proofs of Theorems 1, 2, 3, 5 and 6.
