A general class of quasi-independence tests for left-truncated right-censored data

Young-Geun Choi, Wei-Yann Tsai and Myunghee Cho Paik*

September 11, 2017

Abstract

In survival studies, classical inferences for left-truncated data require quasi-independence, a property that the joint density of truncation time and failure time is factorizable into their marginal densities in the observable region. The quasi-independence hypothesis is testable; many authors have developed tests for left-truncated data with or without right-censoring. In this paper, we propose a class of test statistics for testing the quasi-independence which unifies the existing methods and generates new useful statistics such as conditional Spearman's rank correlation coefficient. Asymptotic normality of the proposed class of statistics is given. We show that a new set of tests can be powerful under certain alternatives by theoretical and empirical power comparison.

Keywords: Conditional Kendall's tau; Conditional product-moment correlation; Left-truncation; Quasi-independence testing; Right-censoring; Survival data.

1 Introduction

Left truncation is a common type of incompleteness in survival analysis along with right-censoring. A typical prevalent cohort study produces left-truncated data. A famous example is the study of the residents of the Channing House retirement community in Palo Alto, California. The subjects who died before becoming eligible for the retirement community cannot be recruited and thus are truncated. Left truncation also induces length-biased sampling (Asgharian et al., 2002; Tsai, 2009). Analysis of left-truncated data with or without right censoring has been studied (Hyde, 1977; Lynden-Bell, 1971; Wang et al., 1986). To accommodate left truncation, a key is to redefine the risk set for truncated data to apply the Kaplan-Meier estimator and Cox proportional hazard models (Andersen et al., 1993). However, these methods assume an independence between failure time and truncation time. Tsai (1990) pointed out

that what we need is a weaker assumption than independence, namely, quasi-independence, which is independence between failure and truncation times only in the observed region.

Unlike independence between failure time and censoring time, quasi-independence is testable. Tsai (1990) proposed a statistic based on the Kendall's tau conditioning on a set of observations that can be interpreted as "comparable" set of data points. Jones and Crowley (1992) presented a score-type test from the Cox proportional hazard model. Chen et al. (1996) suggested a test statistic for quasi-independence based on the conditional product-moment correlation among comparable data points if failure and truncation times follow truncated bivariate normal distribution. Martin and Betensky (2005) extended the conditional Kendall's tau test to more complex truncation schemes. We note that both Tsai (1990) and Chen et al. (1996)'s works adapted usual association measures for complete bivariate data. It may become of interest whether other measures can be adjusted for left truncation and right censoring. However, the following questions remain unclear in general: (1) which association measure for complete bivariate data can be tailored to survival data with left truncation?; (2) if so, in what mechanism the given measure is adjusted?

To address those question, we propose a general class of test statistics that unifies the existing tests and induces some new statistics. The class reveals that any association measure with a form U -statistic comprising skew-symmetric transformations can induce a version for left truncated data, restricting the measure onto the mean among "comparable pairs". The class is broad enough to embed not only existing tests by Tsai (1990), Jones and Crowley (1992) and Chen et al. (1996), but also Spearman's rank correlation, another well-known association measure. We derive asymptotic properties of the proposed class of statistics. We further specify sufficient conditions to guarantee that the proposed class has a valid asymptotic null distribution under right censoring, which is another contribution. We compare various statistics by simulation studies and theoretical efficacies under a sequence of contiguous alternatives.

The remainder of this paper is organized as follows. In Section 2, we introduce notations and review existing quasi-independence tests. In Section 3 we propose the general class of test statistics and derive asymptotic properties. We also introduce new useful statistics derived from the proposed class. In Section 4, we compare asymptotic relative efficiencies of some cases of our class to Kendall's tau under a special case of contiguous excess and relative risk models. In Section 5, we compare the empirical power of the different tests within the class under various alternatives. Section 6 illustrates application of the proposed tests to the Channing House data. Finally, concluding remarks follow in Section 7.

2 Existing methods

In this Section, we review existing methods for quasi-independence testing: conditional Kendall's tau (Tsai, 1990), conditional product-moment correlation coefficient (Chen et al., 1996), and a weighted score test for the Cox proportional hazard model (Jones and Crowley, 1992).

Let (L, X, C) be a tuple of truncation, failure, and censoring times, and $T = \min(X, C)$ and $\delta = I(X \leq C)$ where $I(A)$ is the indicator function for an event A . The quasi-independence hypothesis is described by

$$H_0 : \quad \text{pr}(L \leq l, X \leq x | L \leq X) = \text{pr}(L \leq l)\text{pr}(X \leq x)/\alpha, \quad l < x$$

for some constant α . We suppose that left-truncated data $\{(L_i, X_i)\}_{i=1}^n$ are independently and identically distributed given $L < X$. In the presence of right censoring, left-truncated right-censored data $\{(L_i, X_i, C_i)\}_{i=1}^n$ are assumed to be randomly sampled given $L < X$ where we observe $\{(L_i, T_i, \delta_i)\}_{i=1}^n$. In addition, we assume throughout the paper that

Assumption 1. X and C are independent conditionally on L , and

Assumption 2. $L < C$ with probability 1.

2.1 Conditional Kendall's tau

Kendall's tau is a popular nonparametric measure of association between two random variables. If (X_1, Y_1) and (X_2, Y_2) are independent copies of a bivariate random vector (X, Y) , Kendall's tau is defined by

$$\rho^{\text{Tau}} = E\{\text{sign}(X_1 - X_2)\text{sign}(Y_1 - Y_2)\},$$

where $\text{sign}(t)$ is the sign function, $\text{sign}(t) = I(t > 0) - I(t < 0)$. It is known that if X and Y are independent, then $\rho^{\text{Tau}} = 0$. A consistent estimator of ρ^{Tau} can be obtained by a U -statistic

$$\hat{\rho}^{\text{Tau}} = \frac{1}{\binom{n}{2}} \sum_{i=1}^{n-1} \sum_{j=i+1}^n \text{sign}(X_j - X_i)\text{sign}(Y_j - Y_i).$$

One can construct a test statistic based on $\hat{\rho}^{\text{Tau}}$ to test $\rho^{\text{Tau}} = 0$, and its limiting distribution can be obtained applying the central limit theorem for U -statistic (Randles and Wolfe, 1991).

Tsai (1990) defined conditional Kendall's tau to adjust the Kendall's tau for left-truncated data. Let (L_1, X_1) and (L_2, X_2) be independent copies from the distribution of (L, X) given $L < X$. The conditional Kendall's tau is defined by

$$\begin{aligned} \rho^{\text{CTau}} &= E\{\text{sign}(L_1 - L_2)\text{sign}(X_1 - X_2)|\Omega_{12}\} \\ &= E\{\text{sign}(L_1 - L_2)\text{sign}(X_1 - X_2)I(\Omega_{12})\}/\text{pr}(\Omega_{12}), \end{aligned} \quad (1)$$

where Ω_{12} is an event defined by $\Omega_{12} = \{\max(L_1, L_2) < \min(X_1, X_2)\}$. We call Ω_{12} comparable region. In this region, there is overlap between the two durations. The conditional Kendall's tau measures concordance only in comparable region, Ω_{12} . It is easy to show that $\rho^{\text{CTau}} = 0$ between L and X under the quasi-independence. A consistent estimator of ρ^{CTau} (1) is

$$\begin{aligned}\hat{\rho}^{\text{CTau}} &= \left\{ \frac{1}{\binom{n}{2}} \sum_{i=1}^{n-1} \sum_{j=i+1}^n \text{sign}(L_j - L_i) \text{sign}(X_j - X_i) I(\Omega_{ij}) \right\} / \left\{ \frac{W_n}{\binom{n}{2}} \right\} \\ &= \frac{1}{W_n} \sum_{i=1}^{n-1} \sum_{j=i+1}^n \text{sign}(L_j - L_i) \text{sign}(X_j - X_i) I(\Omega_{ij})\end{aligned}$$

where $W_n = \sum_{i=1}^{n-1} \sum_{j=i+1}^n I(\Omega_{ij})$. As in $\hat{\rho}^{\text{Tau}}$, the conditional version $\hat{\rho}^{\text{CTau}}$ is approximated by a normal distribution from the same central limit theorem. The asymptotic variance of $\hat{\rho}^{\text{CTau}}$ can be obtained as the variance of U -statistic using $O(n^3)$ of Floating-point Operations per Second (flops), where the formula is introduced in the next Section. [Martin and Betensky \(2005\)](#) introduced an analytic technique in which the computation reduces to $O(n^2)$ flops. On the other hand, [Tsai \(1990\)](#) derived another formula for the variance which only involves the numbers of the risk sets of given data and requires at most $O(n^2)$ flops.

Conditional Kendall's tau was adapted to right-censoring by [Tsai \(1990\)](#), and [Martin and Betensky \(2005\)](#) in multivariate case. Having (L_1, T_1, δ_1) and (L_2, T_2, δ_2) as independent copies conditioning on $L < X$, the quantity of interest is

$$\begin{aligned}\kappa^{\text{CTau}} &= E\{\text{sign}(L_1 - L_2) \text{sign}(T_1 - T_2) | \Lambda_{12}\} \\ &= E\{\text{sign}(L_1 - L_2) \text{sign}(T_1 - T_2) I(\Lambda_{12})\} / \text{pr}(\Lambda_{12}),\end{aligned}$$

where Λ_{12} is a comparable region with left truncation and right censoring defined by $\Lambda_{12} = \{\max(L_1, L_2) < \min(T_1, T_2)\} \cap [(\delta_1 \delta_2 = 1) \cup \{\delta_1 \text{sign}(T_2 - T_1) = 1\} \cup \{\delta_2 \text{sign}(T_1 - T_2) = 1\}]$. Due to right censoring, comparable region Λ_{12} is modified from Ω_{12} so that minimum of T_1 and T_2 should be a failed one. As in Ω_{12} , there is overlap between the two durations in Λ_{12} . If L and X are quasi-independent, [Martin and Betensky \(2005\)](#) proved that $\kappa^{\text{CTau}} = 0$ under Assumptions 1 and 2. A consistent estimator of κ^{CTau} is

$$\hat{\kappa}^{\text{CTau}} = \frac{1}{V_n} \sum_{i=1}^{n-1} \sum_{j=i+1}^n \text{sign}(L_j - L_i) \text{sign}(T_j - T_i) I(\Lambda_{ij}), \quad (2)$$

where $V_n = \sum_{i=1}^{n-1} \sum_{j=i+1}^n I(\Lambda_{ij})$.

2.2 Conditional product-moment correlation

[Chen et al. \(1996\)](#) proposed a test based on conditional product-moment correlation coefficient

for left-truncated data. Similarly to Tsai (1990), Chen et al. (1996) first defined the population version of the correlation coefficient conditioning on Ω_{12} ,

$$\rho^{\text{CProd}} = E\{(L_1 - L_2)(X_1 - X_2)|\Omega_{12}\},$$

and proved $\rho^{\text{CProd}} = 0$ under the quasi-independence. They also suggested a consistent estimator

$$\hat{\rho}^{\text{CProd}} = \frac{1}{W_n} \sum_{i=1}^{n-1} \sum_{j=i+1}^n (L_j - L_i)(X_j - X_i)I(\Omega_{ij}).$$

It is noteworthy that Chen et al. (1996) did not extend the test to the right-censored data. As in the case of the conditional Kendall's tau, one might have considered an analogue of ρ^{CProd} for right-censoring, for example, say $\kappa^{\text{CProd}} = E\{(L_1 - L_2)(T_1 - T_2)|\Lambda_{12}\}$. However, in general, $\kappa^{\text{CProd}} \neq 0$ under the quasi-independence, and a similar extension with conditional Kendall's tau fails. In Section 3, we will see that $\kappa^{\text{CProd}} = 0$ holds with additional assumptions.

2.3 Weighted score tests from the Cox proportional hazard model

Jones and Crowley (1992) adopted a class of weighted score tests from the Cox proportional hazard model proposed in Jones and Crowley (1989) to the quasi-independence testing. Consider a conditional hazard function with a time-varying covariate given by

$$\lambda(t | Z_i) = \lambda_0(t) \exp \{Z_i(t)\beta\}, \quad i = 1, \dots, n,$$

where $\lambda(t | Z)$ is the hazard function for X given a predictable covariate function $Z(t)$ and the truncation event $L < X$. Testing $\beta = 0$ yields a score-type test statistic and Jones and Crowley (1989) proposed its weighted version,

$$T^{\text{Cox}}(q, Z) = \sum_{i=1}^n \delta_i q(T_i) \left\{ Z_i(T_i) - \frac{\sum_{j=1}^n Y_j(T_i) Z_j(T_i)}{Y(T_i)} \right\},$$

where $q(t)$ is a predictable weight function, $Y_j(t) = I(L_j < t \leq T_j)$ is the at-risk indicator for the j -th observation at time t , and $Y(t) = \sum_{j=1}^n Y_j(t)$ is the number of subjects at risk for time t . The asymptotic distribution of $T^{\text{Cox}}(q, Z)$ under $\beta = 0$ is derived using the counting process theory. Jones and Crowley (1992) proposed to take a function of truncation time as covariate. Then the quasi-independence is equivalent to $\beta = 0$, which can be tested via the score test, T^{Cox} . The covariates considered in the paper were $Z_i(t) = L_i$ or $Z_i(t) = R_i^*(t)$, where $R_i^*(t) = R_i(t)/Y(t)$ and $R_i(t)$ is the rank of L_i in the risk set defined at t , explicitly, $R_i(t) = 1 + \sum_{j=1}^n Y_j(t)I(L_i < L_j)$. We denote the weighted score statistics with covariate L_i or $R_i^*(t)$ by $T^{\text{Cox}}(q, L)$ and $T^{\text{Cox}}(q, R^*)$, respectively.

3 A general class for quasi-independence tests

A common characteristic from the conditional Kendall's tau and the conditional product-moment correlation is that they have a form of U -statistics among the pairs in a comparable region defined in the presence of left truncation and right censoring. We begin this Section by observing that the tests from the weighted score tests from the Cox proportional hazard model also can be expressed as a U -statistic. Considering $q(t) = Y(t)$, the size of risk set at time t as the weight function, we have

$$T^{\text{Cox}}\{Y, a(L)\} = - \sum_{i=1}^{n-1} \sum_{j=i+1}^n \{a(L_i) - a(L_j)\} \text{sign}(T_i - T_j) I(\Lambda_{ij}) \quad (3)$$

for any real-valued function $a(\cdot)$ and

$$T^{\text{Cox}}(Y, R^*) = -\frac{1}{2} \sum_{i=1}^{n-1} \sum_{j=i+1}^n \text{sign}(L_i - L_j) \text{sign}(T_i - T_j) I(\Lambda_{ij}) + \frac{1}{2} \sum_{i=1}^n \delta_i. \quad (4)$$

The derivation of (3) and (4) is given in the Appendix. Jones and Crowley (1992) discuss the relationship in (4), i.e., $T^{\text{Cox}}(Y, R^*)$ is equivalent to the conditional Kendall's tau. From the two equations, we see that $T^{\text{Cox}}(Y, L)$ and $T^{\text{Cox}}(Y, R^*)$ share the common characteristic of $\hat{\rho}^{\text{CTau}}$, $\hat{\kappa}^{\text{CTau}}$, and $\hat{\rho}^{\text{CProd}}$, namely, U -statistic indexed among comparable pairs adjusting left truncation and right censoring.

Another important common characteristic among the statistics, $\hat{\rho}^{\text{CTau}}$, $\hat{\kappa}^{\text{CTau}}$, $\hat{\rho}^{\text{CProd}}$, $T^{\text{Cox}}(Y, L)$, and $T^{\text{Cox}}(Y, R^*)$, is skew-symmetry of the functions of L_i and L_j , satisfying $g(L_i, L_j) = -g(L_j, L_i)$. To see why the skew-symmetry of g is crucial, let us consider the case of left-truncation without right-censoring. For all those U -statistics, we need their estimands to be zero under quasi-independence to have valid asymptotic null distribution. In taking the expectation, the integral region Ω_{12} can be divided by four subevents, $A_1 = (L_1 < L_2 < X_1 < X_2)$, $A_2 = (L_1 < L_2 < X_2 < X_1)$, $A_3 = (L_2 < L_1 < X_1 < X_2)$, and $A_4 = (L_2 < L_1 < X_2 < X_1)$, flipping the order of L_1 and L_2 , and X_1 and X_2 , under the restriction of comparable region. Then the expectation can be expressed as a sum of four subintegrals associated with the four regions. The skew-symmetry of the mapping function for truncation times renders cancellation of subintegrals from A_1 and A_3 , and similarly from A_2 and A_4 .

Motivated by the common structure of the existing statistics, we propose a class of U -type test statistics that is indexed by skew-symmetric functions. We first present the proposed method for the left-truncated data in Section 3.1 and then for left-truncated and right-censored data in Section 3.2. The cancellation of subintegrals will play a key role when proving the

asymptotic null distribution of the classes. In Section 3.3, we discuss several new tests that are special cases of the proposed class of statistics, including a version of Spearman's rank correlation coefficient.

3.1 Tests for left-truncated data without right-censoring

We assume $\{(L_i, X_i)\}_{i=1}^n$ are observed in region $\{(l, x) : l < x\}$. Let g and h be bivariate skew-symmetric functions, that is, $g(s, t) = -g(t, s)$ and $h(s, t) = -h(t, s)$ for all real s, t . Skew-symmetry of $g(\cdot, \cdot)$ is needed to cancel out subintegrals from subregions as described earlier. We impose skew-symmetry of $h(\cdot, \cdot)$ to satisfy symmetry of U -statistics. Recall the definition $\Omega_{ij} = (\max(L_i, L_j) < \min(X_i, X_j))$. We propose

$$\widehat{\rho}(g, h) = \frac{1}{W_n} \sum_{i=1}^{n-1} \sum_{j=i+1}^n g(L_i, L_j) h(X_i, X_j) I(\Omega_{ij}), \quad (5)$$

where $W_n = \sum_{i=1}^{n-1} \sum_{j=i+1}^n I(\Omega_{ij})$, which estimates

$$\begin{aligned} \rho(g, h) &= E\{g(L_1, L_2)h(X_1, X_2)|\Omega_{12}\} \\ &= E\{g(L_1, L_2)h(X_1, X_2)I(\Omega_{12})\}/\text{pr}(\Omega_{12}). \end{aligned} \quad (6)$$

The special cases of $\rho(g, h)$ include ρ^{CTau} , by choosing $g(s, t) = h(s, t) = \text{sign}(s - t)$ and ρ^{CProd} , $g(s, t) = h(s, t) = s - t$, respectively. Other choices of g and h generate new statistics, which we discuss in Section 3.3.

Theorem 1. *Let $g(\cdot, \cdot)$ and $h(\cdot, \cdot)$ be skew-symmetric bivariate functions and let $\widehat{\rho}(g, h)$ and $\rho(g, h)$ be defined as in (5) and (6). As $n \rightarrow \infty$, $n\widehat{\rho}(g, h)^2/\{4\phi(g, h)/\text{pr}(\Omega_{12})^2\}$ is asymptotically distributed as a chi-squared distribution with 1 degree of freedom under the quasi-independence between L and X , where $\phi(g, h) = E\{g(L_1, L_2)h(X_1, X_2)I(\Omega_{12})g(L_1, L_3)h(X_1, X_3)I(\Omega_{13})\}$, and (L_i, X_i) , $i = 1, 2, 3$ are independent copies of the distribution of (L, X) conditioning on $L < X$.*

A proof is given in the Appendix. A key step in the proof is showing that $\rho(g, h) = 0$ under the quasi-independence between L and X using skew-symmetry of function g , following by the central limit theorem for one-sample U -statistic (Randles and Wolfe, 1991). We can replace $\text{pr}(\Omega_{12})$ and $\phi(g, h)$ with $\widehat{\text{pr}}(\Omega_{12}) = \sum_{i < j} I(\Omega_{ij})/\binom{n}{2}$ and $\widehat{\phi}(g, h) = \sum_{i < j < k} a_{ij}b_{ik}/\binom{n}{3}$, where $a_{ij} = b_{ij} = g(L_i, L_j)h(X_i, X_j)I(\Omega_{ij})$, and the Theorem still holds after applying Slutsky's theorem. Martin and Betensky (2005) reduced the burden of computation of $\widehat{\phi}(g, h)$ with $O(n^3)$ flops to $O(n^2)$ flops with

$$\sum_{i=1}^n \sum_{j \neq i} \sum_{k \neq i} a_{ij}b_{ik} = \sum_{i=1}^n (a_i \cdot b_i - c_i), \quad (7)$$

where $a_{i\cdot} = \sum_{j \neq i} a_{ij}$, $b_{i\cdot} = \sum_{j \neq i} b_{ij}$, and $c_{i\cdot} = \sum_{j \neq i} a_{ij}b_{ij}$.

3.2 Tests for left-truncated right-censored data

Given $\{(L_i, T_i, \delta_i)\}_{i=1}^n$, we propose

$$\widehat{\kappa}(g, h) = \frac{1}{V_n} \sum_{i=1}^{n-1} \sum_{j=i+1}^n g(L_i, L_j)h(T_i, T_j)I(\Lambda_{ij}),$$

where $V_n = \sum_{i=1}^{n-1} \sum_{j=i+1}^n I(\Omega_{ij})$ and $\Lambda_{ij} = \{\max(L_i, L_j) < \min(T_i, T_j)\} \cap [(\delta_i\delta_j = 1) \cup \{\delta_i \text{sign}(T_j - T_i) = 1\} \cup \{\delta_j \text{sign}(T_i - T_j) = 1\}]$. Technically speaking, $\widehat{\rho}(g, h)$ is a special case of $\widehat{\kappa}(g, h)$ with assigning $\delta_i = 1$ for all i . Similarly to the case of $\widehat{\rho}(g, h)$, $\widehat{\kappa}(g, h)$ consistently estimates

$$\kappa(g, h) = E[g(L_1, L_2)h(T_1, T_2)I(\Lambda_{12})]/\text{pr}(\Lambda_{12}).$$

In addition to Assumptions 1 and 2, we suppose the following:

Assumption 3. *Either (3A) $h(s, t) = \text{sign}(s - t)$ or (3B) L and C are quasi-independent.*

Then we have the following theorem:

Theorem 2. *Let $g(\cdot, \cdot)$ and $h(\cdot, \cdot)$ be skew-symmetric bivariate functions and Assumption 3 holds. As $n \rightarrow \infty$, $n\widehat{\kappa}(g, h)^2/\{4\varphi(g, h)/\text{pr}(\Lambda_{12})^2\}$ is asymptotically distributed as a chi-squared distribution with 1 degree of freedom under the quasi-independence between L and X , where $\varphi(g, h) = E\{g(L_1, L_2)h(T_1, T_2)I(\Lambda_{12})g(L_1, L_3)h(T_1, T_3)I(\Lambda_{13})\}$, and (L_i, T_i, δ_i) , $i = 1, 2, 3$ are independent copies of the distribution from (L, T, δ) conditioning on $L < X$.*

A sketch of a proof of is given in the Appendix. As in Theorem 1, a key idea is to show $\kappa(g, h) = 0$ under the quasi-independence between L and X given Assumption 3 in addition to 1 and 2. We can show that $\kappa(g, h)$ becomes zero under quasi-independence with Assumption 3A using the skew-symmetry of $g(\cdot, \cdot)$. If $h(\cdot, \cdot)$ is a skew-symmetric function other than the sign function as in the conditional product-moment correlation, we need extra assumption, Assumption 3B. By Slutsky's theorem, we can replace $\varphi(g, h)$ and $\text{pr}(\Lambda_{12})$ with respective consistent estimators, $\widehat{\text{pr}}(\Lambda_{12}) = \sum_{i < j} I(\Lambda_{ij})/\binom{n}{2}$ and $\widehat{\varphi}(g, h) = \sum_{i < j < k} a_{ij}b_{ik}/\binom{n}{3}$, where $a_{ij} = b_{ij} = g(L_i, L_j)h(T_i, T_j)I(\Lambda_{ij})$.

3.3 New test statistics and a unifying framework

We mentioned that the test statistics $\widehat{\rho}(g, h)$ and $\widehat{\kappa}(g, h)$ embed the existing tests described in Section 2. Other choices of g and h generate several new useful tests. We highlight the following examples:

Example 1. Let $g(L_i, L_j) = L_i - L_j$ and $h(T_i, T_j) = T_i - T_j$. Then $\widehat{\kappa}(L_i - L_j, T_i - T_j)$ can be viewed as an extension of the conditional production-moment correlation test accommodating right censoring.

Example 2. Consider a rank difference function, $r(X_i, X_j) = \text{rank}(X_i)/n - \text{rank}(X_j)/n$, where $\text{rank}(X_i)$ is the rank of X_i among a dataset $\{X_i\}_{i=1}^n$. The function $\text{rank}(\cdot)/n$ approximates the cumulative distribution function of X , F_X . Then $\widehat{\rho}\{r(L_i, L_j), r(T_i, T_j)\}$ and $\widehat{\kappa}\{r(L_i, L_j), r(T_i, T_j)\}$ correspond to Spearman’s rank correlation coefficient adapted to left-truncated data and to left-truncated and right-censored data, respectively, measuring the correlation among comparable pairs. The proposed test is likely to inherit advantages of Spearman’s rank correlation compared for non-truncated data such as effectively detecting nonlinear dependence between two variables.

Example 3. One can also consider a hybrid of the Kendall’s tau and the rank correlation, $\widehat{\rho}\{r(L_i, L_j), \text{sign}(X_i - X_j)\}$ and $\widehat{\kappa}\{r(L_i, L_j), \text{sign}(T_i - T_j)\}$. An advantage of the hybrid statistic $\widehat{\kappa}\{r(L_i, L_j), \text{sign}(T_i - T_j)\}$ does not require Assumption 3B, as the rank correlation $\widehat{\kappa}(r(L_i, L_j), r(T_i, T_j))$ in Example 2 does.

Table 1 summarizes existing approaches and the new tests according to the choice of g and h , where “sign”, “rank” and “linear” functions in the second and third column are defined by $\text{sign}(s - t)$, $\text{rank}(s)/n - \text{rank}(t)/n$, and $s - t$, respectively, for real s and t . The three dependence measures on bivariate data, Kendall’s tau, Spearman’s rank correlation, and Pearson’s product-moment correlation, are systemically adjusted in our proposed test statistics.

Table 1: Special cases of the proposed class. The “sign”, “linear”, and “rank” functions denote bivariate mappings $\text{sign}(s - t)$, $s - t$, and $r(s, t)$ defined in Section 3.3, respectively. Tests requiring additional Assumption 3B are marked with asterisk(*).

4 Asymptotic relative efficiencies

The fact that we can specify g and h leads to a natural question, which choice of g and h would be suitable to improve power to reject the quasi-independent hypothesis. For complete bivariate data, [Randles and Wolfe \(1991\)](#) reported that Spearman's rank correlation and Kendall's tau had asymptotically comparable powers. The asymptotic relative efficiency of the rank correlation to the product-moment correlation was 0.91 when the assumptions for the latter were satisfied ([Daniel, 1990](#); [Siegel and Castellan, 1988](#)). For left-truncated survival data, [Jones and Crowley \(1992\)](#) reported that $T^{\text{Cox}}(q, L)$ with suitable choice of weight function q is more efficient than the conditional Kendall's tau test. They used [Jones and Crowley \(1990\)](#)'s formula for asymptotic power under local contiguous alternatives.

We use the approach of [Jones and Crowley \(1990\)](#) and [Jones and Crowley \(1992\)](#) to compare the theoretical powers of our proposed test statistics. If h is the sign function, the proposed $\widehat{\rho}(g, \text{sign})$ and $\widehat{\kappa}(g, \text{sign})$ has equivalent form to [Jones and Crowley \(1992\)](#)'s test statistic, T^{Cox} , as seen in (3) and (4) for several choices of g . We restrict our interest to the case of $g(L_i, L_j)$ being one of the followings: (1) $\text{sign}(L_i - L_j)$ ("sign"); (2) $r(L_i, L_j)$ which is eventually approximated to $F_L(L_i) - F_L(L_j)$ ("rank"); and (3) $L_i - L_j$ ("linear"). We consider a sequence of contiguous hazard alternatives,

$$H_1^n : \lambda(t | L_i) = \lambda_1(t) \{ \alpha_1(t) + n^{-1/2} a(L_i) \beta + O(n^{-1}) \},$$

where $a(\cdot)$ is a real-valued measurable function. The given alternative has been called as a relative risk model if $\alpha_1(t) = 1$ and an excess risk model if $\lambda_1(t) = 1$. Following similar arguments to [Jones and Crowley \(1990\)](#), we can show that the three test statistics converge in distribution to the normal distribution with mean $\mu(\infty)/\sigma(\infty)$ and variance 1, where $\mu(t)$ and $\sigma(t)^2$ are calculated as in Table 2. We introduce further notations in the table: $\bar{y}(t)$ is the limit of proportion of subjects at risk at time t ; $\sigma_{XY}(t)$ is the limit of covariance of $X_i(t)$'s and $Y_i(t)$'s at risk at time t for two processes $X(t)$ and $Y(t)$. For completeness, we present the definitions stated in [Jones and Crowley \(1992\)](#):

$$\sigma_{XY}(t) = \int_0^t X(l)Y(l)f_t(l)dl - \left(\int_0^t X(l)f_t(l)dl \right) \left(\int_0^t Y(l)f_t(l)dl \right),$$

$$\text{where } f_t(l) = I(l < t) \frac{\exp \left\{ - \int_0^l \Gamma_0(x)dx - \int_l^t \Gamma_1(x)dx \right\} \theta(l) \exp \left\{ - \int_0^l \theta(x)dx \right\}}{\int_0^t \exp \left\{ - \int_0^l \Gamma_0(x)dx - \int_l^t \Gamma_1(x)dx \right\} \theta(l) \exp \left\{ - \int_0^l \theta(x)dx \right\} dl} \quad (8)$$

with $\Gamma_i(x) = \psi_i(x) + \lambda_i(x)$ for $i = 0, 1$. Here, $\theta(t)$ is the hazard function of L , $\lambda_0(t)$ is the hazard rate of failure time of subjects who did not entered the study, and $\psi_1(t)$ and $\psi_0(t)$ are the

hazard rates of censoring times of subjects who did and did not enter the study. Another note is that $\bar{y}(t)$ is the determinant of (8). The efficacy of a given test is defined as $\mu(\infty)^2/\sigma(\infty)^2$. We will compare the efficacies of the tests by Pitman asymptotic relative efficiency, the ratio of the efficacy of a test to another.

$\widehat{\kappa}(g, h)$		Equivalent form	$\mu(t)$ and $\sigma^2(t)$
$g(\cdot, \cdot)$	$h(\cdot, \cdot)$	in $T^{\text{Cox}}(q, Z)$	
Sign	Sign	$T^{\text{Cox}}(Y, R^*)$	$\mu(t) = \beta \int_0^t \bar{y}^2(u) \sigma_{a(L)R^*}(u) \lambda_1(u) du$ $\sigma(t)^2 = \int_0^t \bar{y}(u)^3 \sigma_{R^*R^*}(u) \lambda_1(u) \alpha_1(u) du$
Rank	Sign	$T^{\text{Cox}}(Y, F_L(L))$	$\mu(t) = \beta \int_0^t \bar{y}(u)^2 \sigma_{a(L)F(L)}(u) \lambda_1(u) du$ $\sigma(t)^2 = \int_0^t \bar{y}(u)^3 \sigma_{F(L)F(L)}(u) \lambda_1(u) \alpha_1(u) du$
Linear	Sign	$T^{\text{Cox}}(Y, L)$	$\mu(t) = \beta \int_0^t \bar{y}(u)^2 \sigma_{a(L)L}(u) \lambda_1(u) du$ $\sigma(t)^2 = \int_0^t \bar{y}(u)^3 \sigma_{LL}(u) \lambda_1(u) \alpha_1(u) du$

Table 2: Asymptotic efficacies for the select cases of the proposed class. Notations are defined in the main body of the paper.

We considered the following submodels of the contiguous alternatives:

- Model 1 (M1): $\lambda(t | L_i) = 0.3 \cdot (1 + n^{-1/2} L_i \beta)$,
- Model 2 (M2): $\lambda(t | L_i) = 0.3 \cdot \{1 + n^{-1/2} (L_i^2 + \sin L_i)^{-1} \beta\}$,

Both models are special cases of a relative risk or an excess risk model; M1 was selected to consider a model linear in L and M2 was for one nonlinear in L . We generated L from either the exponential distribution with rate 2 or the uniform distribution on $[0, 1]$. We chose $\lambda_0(t) = 0.3$ and $(\psi_0(t), \psi_1(t))$ as $(0, 0)$, $(0, 1)$, and $(1, 1)$ following Jones and Crowley (1992). If $\psi_1(t) = 0$, there is no censoring on the observed patients and the resulting efficacies corresponds to those from the proposed class with no censoring. Similarly, by $\psi_1(t) = 1$ we can compare the efficacies from censored data. In those settings, we could calculate the given $\mu(t)$'s and $\sigma(t)^2$'s under M1 by simple algebra and formulas given in Appendix 2 in Jones and Crowley (1992). For M2, we approximated them by numerical integration.

Table 3 displays asymptotic relative efficiencies to $\widehat{\kappa}\{\text{sign}(L_i - L_j), \text{sign}(T_i - T_j)\}$ that is equivalent to the conditional Kendall's tau. We first focus on the case of $L \sim \text{Exp}(2)$. The choice of g as the rank function, $g(L_i, L_j) = F_L(L_i) - F_L(L_j)$, performed better than and comparable to the conditional Kendall's tau when under M1 and M2, respectively. For the cases of $g(L_i, L_j) = L_i - L_j$ (the linear function), it performed the best under M1 where the dependence is linear and worst under M2 that depends on L nonlinearly. When L was uniform on $[0, 1]$, we have $F_L(L) = L$ and the efficacies from g as the rank and linear functions are

theoretically the same. Their performance was slightly better than or similar to that of the conditional Kendall’s tau. From this limited comparison, we could see that the choice of g as the linear function may lead to more powerful test under linear relationship between L and T , but lead to a poor performance under certain nonlinear alternatives. On the other hand, the choice of g as the rank function performed better in some nonlinear cases.

Model	$g(\cdot, \cdot)$	$h(\cdot, \cdot)$	True distribution					
			L (ψ_0, ψ_1)	Exp(2)		Unif(0, 1)		
			(0, 1)	(0, 1)	(1, 1)	(0, 0)	(0, 1)	(1, 1)

Table 3: Asymptotic relative efficiencies of selected $\hat{\kappa}(g, h)$ ’s relative to $\hat{\kappa}\{\text{sign}(L_i - L_j), \text{sign}(T_i - T_j)\}$ (Kendall’s tau).

5 Simulation study

We evaluated finite sample performances of the proposed test statistics $\hat{\rho}(g, h)$ and $\hat{\kappa}(g, h)$ with g and h chosen as in Table 1. Simulation scenarios mimic those of Jones and Crowley (1992) and Chen et al. (1996).

Pairs of (L, X) were generated from the following two null and three non-null scenarios. We considered three exponential models where L is uniformly generated from $[0, 5]$ with the hazard function x as $h(x|L) = 0.3$, $h(x|L) = 0.3(1 - L/12)$, and $h(x|L) = 0.3\{(L - 2.5)^2 + 2\}^{-1}$, respectively. The first scenario represents the null case, the following two represent linear and nonlinear alternative cases. We also considered two normal models where $(L, X)^T$ follows a multivariate normal distribution with mean $(-1, 0)^T$ and covariance matrices as $[1, \rho; \rho, 1]$, for $\rho = 0, 0.15$, representing null and alternative cases, respectively.

For left-truncated and right-censored data, censoring time C was independently generated from an exponential distribution, keeping the censoring rate around 40%. Finally, observations with $L \geq \min(X, C)$ were discarded. Sample size after the truncation was set to 400. For the generated dataset, we calculated the five $\hat{\rho}(g, h)$ ’s and $\hat{\kappa}(g, h)$ ’s with the choices of g and h presented in Table 1 and conducted the quasi-independence hypothesis testing at the significance level 5% according to the asymptotic null distribution shown in the Theorems.

Table 4 reports empirical rejection rates over 5000 replications for the tests under the aforementioned five null and alternative scenarios. Under the null, all the tests showed the

rejection rates close to the nominal level. Under the alternative, there is no uniformly most powerful test, but depending on the alternatives, different tests had higher power than the others. First, the conditional product-moment correlation was the most powerful under the normal alternative and the exponential alternative where the relationship between L and X was linear. The newly proposed conditional Spearman’s rank correlation featured in Example 2 was the most powerful under the exponential alternative where the relationship between L and X was nonlinear. The results were consistent for both left-truncated and left-truncated and right-censored data. When we restricted comparisons among the tests not requiring Assumption 3B for left-truncated and right-censored data, the hybrid test with g as linear and h as sign, was the most powerful under the normal alternative and the exponential alternative with the linear link. The new test with g as rank and h as sign featured in Example 3 was the most powerful under the exponential alternative with nonlinear link and as powerful as the conditional Kendall’s tau. These findings are consistent with those in Section 4. Summarizing the results, newly proposed tests can be more powerful than existing ones under certain sets of alternatives.

Table 4: Empirical rejection rates of the test statistics $\widehat{\rho}(g, h)$ and $\widehat{\kappa}(g, h)$ with 5,000 simulated datasets from two null and three alternative scenarios, with $g(\cdot, \cdot)$ and $h(\cdot, \cdot)$ chosen according to Table 1. Tests requiring Assumption 3B are marked with asterisk (*). Abbreviations: Exp., exponential model; Norm., normal model; L, linear; NL, nonlinear.

6 Data example: Channing House

We applied the proposed quasi-independence tests to the Channing House data (Hyde, 1980) that include ages at death of 97 males and 365 females who were residents of the Channing House retirement center from January 1964 to July 1975. The data are left-truncated since a

subject who died before entering the community could not be recruited. In addition, the ages at death were right-censored by the end of the study.

Table 5 shows the p -values of the five $\widehat{\kappa}(g, h)$'s. The tests with h as the sign function show that the quasi-independence is marginally significant among the male group but not significant among the female group. The other two tests where h is not the sign function show a strong association between ages at entrance and death. Since these tests are valid under Assumption 3B, that is quasi-independence between censoring and truncation times, we inspected validity of this assumption by reversing the role of survival time and censoring times and applying the tests $\widehat{\kappa}(g, h)$ with h as the sign function. Table 6 displays corresponding p -values and suggests that the quasi-independence between L and C can be rejected. Based on this finding, we adopted the results from the tests which does not require Assumption 3B, and concluded that among women, we fail to reject that failure time and truncation time are quasi-independent.

$\widehat{\kappa}(g, h)$		Evaluated test statistic (p -value)	
$g(\cdot, \cdot)$	$h(\cdot, \cdot)$	Men	Women

7 Concluding remarks

We proposed a general class of tests which can embed existing tests for quasi-independence of truncation time and survival time. The proposed class was built upon common characteristics of existing tests, namely, U -statistics of skew-symmetric transforms of all the pairs of comparable observations. For left-truncated and right-censored data, a subclass of tests in which $h(\cdot, \cdot)$ is not the sign function require an additional assumption of quasi-independence between

truncation and censoring times. This subclass can be used after testing quasi-independence between truncation and censoring times via the proposed test with $h(\cdot, \cdot)$ as the sign function exchanging the role of failure and censoring times. We also compared the powers from several choices of g and h theoretically and empirically. Our results suggest that the choice of the linear function may give a good power when the data has linear relationship, and a new sets of tests utilizing the rank function can be powerful under certain nonlinear alternatives. The results resonate with those on Pearson's product-limit correlation, Spearman's rank correlation, and Kendall's tau in complete bivariate data. Further research is needed to better understand when which choices of g and h would be suitable in variety of settings not considered in this paper.

Appendix

A. Proofs of the main results

Proof of (3). Observe that

$$\begin{aligned}
 T^{\text{Cox}}\{Y, a(L)\} &= \sum_{i=1}^n \delta_i Y(T_i) \left\{ a(L_i) - \frac{\sum_{j=1}^n Y_j(T_i) a(L_j)}{Y(T_i)} \right\} \\
 &= \sum_{i=1}^n \delta_i \sum_{j=1}^n Y_j(T_i) \{a(L_i) - a(L_j)\} \\
 &= \sum_{i=1}^n \sum_{j=1}^n \delta_i I(L_j < T_i) I(T_i \leq T_j) \{a(L_i) - a(L_j)\}. \tag{9}
 \end{aligned}$$

For further simplification, we denote $Q(i, j) = \delta_i I(L_j < T_i) I(T_i \leq T_j)$. We see that $Q(i, i) = 0$, and $I(\Lambda_{ij}) = 1$ is equivalent to either $Q(i, j) = 1$ or $Q(j, i) = 1$ for $i \neq j$. Also, without ties, $I(T_i \leq T_j) = I(T_i < T_j) = -I(T_i < T_j) \text{sign}(T_i - T_j)$. These identities leads (9) to

$$\begin{aligned}
 T^{\text{Cox}}\{Y, a(L)\} &= - \sum_{i=1}^n \sum_{j=1}^n \{a(L_i) - a(L_j)\} \text{sign}(T_i - T_j) Q(i, j) \\
 &= - \sum_{i=1}^{n-1} \sum_{j=i+1}^n \{a(L_i) - a(L_j)\} \text{sign}(T_i - T_j) I(\Lambda_{ij}).
 \end{aligned}$$

□

Proof of (4). Recalling the definition of $R_i(t)$, one notes that $\sum_{i=1}^n Y_i(t) R_i(t) = 1 + \dots + Y(t) = Y(t)\{Y(t) + 1\}/2$. In addition, $2I(L_i < L_j) - 1 = -\text{sign}(L_i - L_j)$ from the no-tie assumption.

Then we have

$$\begin{aligned}
 T^{\text{Cox}}(Y, R^*) &= \sum_{i=1}^n \delta_i Y(T_i) \left\{ \frac{R_i(T_i)}{Y(T_i)} - \frac{\sum_{j=1}^n Y_j(T_i) R_j(T_i)}{Y(T_i)^2} \right\} \\
 &= \frac{1}{2} \sum_{i=1}^n \delta_i \{2R_i(T_i) - Y(T_i) - 1\} \\
 &= \frac{1}{2} \sum_{i=1}^n \delta_i \left[\sum_{j=1}^n Y_j(T_i) \{2I(L_i < L_j) - 1\} + 1 \right] \\
 &= -\frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n \delta_i I(L_j < T_i) I(T_i \leq T_j) \text{sign}(L_i - L_j) + \frac{1}{2} \sum_{i=1}^n \delta_i. \quad (10)
 \end{aligned}$$

The left term in (10) has similar form with (9) and it is easy to see $\sum_{i=1}^n \sum_{j=1}^n \delta_i I(L_j < T_i) I(T_i \leq T_j) \text{sign}(L_i - L_j) = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \text{sign}(L_i - L_j) \text{sign}(T_i - T_j) I(\Lambda_{ij})$. \square

Proof of Theorem 1. Let Assumptions 1 and 2, and the quasi-independence hypothesis hold throughout the proof. For simplicity, we consider continuous random variables so that (L, X) has a joint density $f_{L,X}(l, x)$.

By the central limit theorem for one-sample U -statistics (Randles and Wolfe, 1991), as $n \rightarrow \infty$,

$$\sqrt{n}(\hat{\rho}(g, h) - \rho(g, h)) \xrightarrow{d} \mathcal{N}\left(0, \frac{4\zeta}{\text{pr}(\Omega_{12})^2}\right),$$

where $\zeta = \phi(g, h) - [\rho(g, h)\text{pr}(\Omega_{12})]^2$. The theorem holds if $\rho(g, h) = 0$. We claim

$$E[g(L_1, L_2)h(X_1, X_2)I(\Omega_{12})] = 0, \quad (11)$$

which means that the numerator of $\rho(g, h)$ vanishes. Partition the event Ω_{12} into four disjoint events: $A_1 = (L_1 < L_2 < X_1 < X_2)$, $A_2 = (L_1 < L_2 < X_2 < X_1)$, $A_3 = (L_2 < L_1 < X_1 < X_2)$, and $A_4 = (L_2 < L_1 < X_2 < X_1)$. Note that $I(\Omega_{12}) = I(A_1) + I(A_2) + I(A_3) + I(A_4)$. In addition, the quasi-independence implies that $f_{L,X}(l, x) = f_L(l)f_X(x)/\alpha$ on $\{(l, x) : l < x\}$ for some α , where f_L and f_X are marginal densities of L and X , respectively. By the skew-symmetry of g ,

we have

$$\begin{aligned}
& E\{g(L_1, L_2)h(X_1, X_2)I(A_1)\} \\
&= \int_{l_1 < l_2 < x_1 < x_2} g(l_1, l_2)h(x_1, x_2)f_{L,X}(l_1, x_1)f_{L,X}(l_2, x_2)d(l_1, l_2, x_1, x_2) \\
&= \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} \int_{x_2=x_1}^{\infty} g(l_1, l_2)h(x_1, x_2)f_X(x_1)f_L(l_1)f_X(x_2)f_L(l_2)dx_2dx_1dl_2dl_1 \\
&= \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} \int_{x_2=x_1}^{\infty} \{-g(l_2, l_1)\}h(x_1, x_2)f_X(x_1)f_L(l_1)f_X(x_2)f_L(l_2)dx_2dx_1dl_2dl_1 \\
&\stackrel{l_1 \leftrightarrow l_2}{=} \frac{1}{\alpha^2} \int_{l_2=0}^{\infty} \int_{l_1=l_2}^{\infty} \int_{x_1=l_1}^{\infty} \int_{x_2=x_1}^{\infty} \{-g(l_1, l_2)\}h(x_1, x_2)f_X(x_1)f_L(l_2)f_X(x_2)f_L(l_1)dx_2dx_1dl_1dl_2 \\
&= - \int_{l_2 < l_1 < x_1 < x_2} g(l_1, l_2)h(x_1, x_2)f_{L,X}(l_1, x_1)f_{L,X}(l_2, x_2)d(l_1, l_2, x_1, x_2) \\
&= -E\{g(L_1, L_2)h(X_1, X_2)I(A_3)\},
\end{aligned}$$

which implies $E[g(L_1, L_2)h(X_1, X_2)\{I(A_1) + I(A_3)\}] = 0$. A similar argument holds for A_2 and A_4 . Thus (11) holds and the theorem follows. \square

Proof of Theorem 2. The proof goes in a similar way with that for Theorem 1. The asymptotic normality is straightforward from the central limit theorem. Our goal is to show

$$E[g(L_1, L_2)\text{sign}(T_1, T_2)I(\Lambda_{12})] = 0 \quad (12)$$

which implies $\kappa(g, h) = 0$. We continue to suppose Assumption 1 and 2 along with the quasi-independence. For convenience, let (L, X, C) be continuous and has a joint density $f_{L,X,C}(l, x, c)$.

First, suppose that Assumption 3A holds. We verify (12) by proving the two facts: (a) $E\{g(L_1, L_2)\text{sign}(T_1 - T_2)I(\Lambda_{12})\} = E\{g(L_1, L_2)\text{sign}(X_1 - X_2)I(\Lambda_{12})\}$; and (b) $E\{g(L_1, L_2)h(X_1, X_2)I(\Lambda_{12})\} = 0$ for any skew-symmetric g and h .

For (a), write $\Lambda_{12} = B_1 \cup B_2 \cup B_3 \cup B_4$, where the four disjoint events are defined as follows: $B_1 = (L_1 < L_2 < X_1 < T_2) \cap (\delta_1 = 1)$, $B_2 = (L_1 < L_2 < X_2 < T_1) \cap (\delta_2 = 1)$, $B_3 = (L_2 < L_1 < X_1 < T_2) \cap (\delta_1 = 1)$, and $B_4 = (L_2 < L_1 < X_2 < T_1) \cap (\delta_2 = 1)$. Observe that on B_1 , we have $X_1 = T_1 < T_2 < X_2$ which implies $\text{sign}(T_2 - T_1) = \text{sign}(X_2 - X_1) = 1$. Similar arguments hold for B_2, B_3 , and B_4 . Thus $E[g(L_1, L_2)\text{sign}(T_1 - T_2)I(\Lambda_{12})] = E[g(L_1, L_2)\text{sign}(X_1 - X_2)I(\Lambda_{12})]$.

For (b), combine Assumption 1, 2, and the quasi-independence hypothesis to obtain $f_{L,X,C}(l, x, c) = f_X(x)f_{L,C}(l, c)/\alpha$ on $\{(l, x, c) : l < x, l < c\}$ for some α , where f_X and $f_{L,C}$ are the marginal densities of X and (L, C) , respectively. In addition, note that $B_1 = (L_1 < L_2 < X_1 <$

$\min\{X_2, C_1, C_2\}$) and the other disjoint events can be written similarly. We now claim $E[g(L_1, L_2)h(X_1, X_2)I(B_3)] = 0$. Observe that

$$\begin{aligned} & E\{g(L_1, L_2)h(X_1, X_2)I(B_1)\} \\ &= \int_{l_1 < l_2 < x_1 < \min\{x_2, c_1, c_2\}} g(l_1, l_2)h(x_1, x_2)f_{L,X,C}(l_1, x_1, c_1)f_{L,X,C}(l_2, x_2, c_2)dl_1, x_1, c_1, l_2, x_2, c_2 \\ &= \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} \int_{x_2=x_1}^{\infty} \int_{c_1=x_1}^{\infty} \int_{c_2=x_1}^{\infty} g(l_1, l_2)h(x_1, x_2) \cdot \\ & \quad f_X(x_1)f_{L,C}(l_1, c_1)f_X(x_2)f_{L,C}(l_2, c_2)dc_2dc_1dx_2dx_1dl_2dl_1 \\ &= \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} g(l_1, l_2)f_X(x_1)\text{pr}(x_1)Q(l_1, x_1)Q(l_2, x_1)dx_1dl_2dl_1 \end{aligned}$$

where $Q(l, x) = \int_{c=x}^{\infty} f_{L,C}(l, c)dc$ and $\text{pr}(x) = \int_{u=x}^{\infty} h(x, u)f_X(u)du$. On the other hand, the expectation on B_3 can be calculated by

$$\begin{aligned} & E\{g(L_1, L_2)h(X_1, X_2)I(B_3)\} \\ &= \frac{1}{\alpha^2} \int_{l_2=0}^{\infty} \int_{l_1=l_2}^{\infty} \int_{x_1=l_1}^{\infty} g(l_1, l_2)f_X(x_1)\text{pr}(x_1)Q(l_1, x_1)Q(l_2, x_1)dx_1dl_1dl_2 \\ &\stackrel{l_1 \leftrightarrow l_2}{=} \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} g(l_2, l_1)f_X(x_1)\text{pr}(x_1)Q(l_2, x_1)Q(l_1, x_1)dx_1dl_2dl_1 \\ &= \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} \{-g(l_1, l_2)\} f_X(x_1)\text{pr}(x_1)Q(l_2, x_1)Q(l_1, x_1)dx_1dl_2dl_1 \\ &= -E\{g(L_1, L_2)h(X_1, X_2)I(B_1)\}, \end{aligned}$$

where the skew-symmetry of g was used at the third inequality. Thus the claim holds and similarly $E[g(L_1, L_2)h(X_1, X_2)\{I(B_2) + I(B_4)\}] = 0$, which implies (12). \square

Now we consider the case when Assumption 3B holds. Integrating Assumption 1, 2, and 3B, $f_{L,X,C}(l, x, c)$ is equal to $f_L(l)f_X(x)f_C(c)/\alpha$ on $\{(l, x, c) : l < x, l < c\}$ for some α , where f_L, f_X, f_C is the marginal densities of L, X and C , respectively. Then

$$\begin{aligned} & E\{g(L_1, L_2)h(T_1, T_2)I(B_1)\} \\ &= \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} \int_{x_2=x_1}^{\infty} \int_{c_1=x_1}^{\infty} \int_{c_2=x_1}^{\infty} g(l_1, l_2)h(x_1, \min(x_2, c_2)) \cdot \\ & \quad f_X(x_1)f_L(l_1)f_C(c_1)f_X(x_2)f_L(l_2)f_C(c_2)dc_2dc_1dx_2dx_1dl_2dl_1 \\ &= \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} \int_{x_2=x_1}^{\infty} g(l_1, l_2)f_X(x_1)f_L(l_1)f_X(x_2)f_L(l_2) \cdot \\ & \quad \left\{ \int_{c_1=x_1}^{\infty} f_C(c_1)dc_1 \right\} \left\{ \int_{c_2=x_1}^{\infty} h(x_1, \min(x_2, c_2))f_C(c_2)dc_1 \right\} dx_2dx_1dl_2dl_1 \end{aligned}$$

On the other hand, on B_3 , interchanging $l_1 \leftrightarrow l_2$ and the skew-symmetry of g yields

$$\begin{aligned}
 & E\{g(L_1, L_2)h(T_1, T_2)I(B_3)\} \\
 = & \frac{1}{\alpha^2} \int_{l_2=0}^{\infty} \int_{l_1=l_2}^{\infty} \int_{x_1=l_1}^{\infty} \int_{x_2=x_1}^{\infty} g(l_1, l_2) f_X(x_1) f_L(l_1) f_X(x_2) f_L(l_2) \cdot \\
 & \left\{ \int_{c_1=x_1}^{\infty} f_C(c_1) dc_1 \right\} \left\{ \int_{c_2=x_1}^{\infty} h(x_1, \min(x_2, c_2)) f_C(c_2) dc_2 \right\} dx_2 dx_1 dl_1 dl_2 \\
 = & \frac{1}{\alpha^2} \int_{l_1=0}^{\infty} \int_{l_2=l_1}^{\infty} \int_{x_1=l_2}^{\infty} \int_{x_2=x_1}^{\infty} g(l_2, l_1) f_X(x_1) f_L(l_2) f_X(x_2) f_L(l_1) \cdot \\
 & \left\{ \int_{c_1=x_1}^{\infty} f_C(c_1) dc_1 \right\} \left\{ \int_{c_2=x_1}^{\infty} h(x_1, \min(x_2, c_2)) f_C(c_2) dc_2 \right\} dx_2 dx_1 dl_1 dl_2 \\
 = & -E\{g(L_1, L_2)h(T_1, T_2)I(B_1)\}.
 \end{aligned}$$

The rest of the proof goes in a same way with the previous proofs and we have (12). \square

\square
