# VARIABLE SELECTION IN ROBUST JOINT MEAN AND COVARIANCE MODEL FOR LONGITUDINAL DATA ANALYSIS 

Xueying Zheng, Wing Kam Fung and Zhongyi Zhu

Supplementary Material

## S1 Sketch of proofs

Following Johnson, Lin, and Zeng (2008), we employ a zero-crossing estimator $\hat{\theta}$ to the penalized estimating equation if, for $j=1, \ldots, s$,

$$
\overline{\lim }_{\varepsilon \rightarrow 0^{+}} \frac{1}{m} U_{j}\left(\hat{\theta}+\varepsilon e_{j}\right) U_{j}\left(\hat{\theta}-\varepsilon e_{j}\right) \leq 0
$$

where $U_{j}$ is the $j$ th component of $U(\cdot)$ and $e_{j}$ is the $j$ th canonical unit vector. Furthermore, an approximate zero-crossing estimator $\hat{\theta}$ is defined if

$$
\varlimsup_{m \rightarrow \infty} \varlimsup_{\varepsilon \rightarrow 0^{+}} \frac{1}{m} U_{j}\left(\hat{\theta}+\varepsilon e_{j}\right) U_{j}\left(\hat{\theta}-\varepsilon e_{j}\right) \leq 0
$$

It is obvious that when $U$ is continuous, the zero-crossing estimator is the same as an exact solution to the penalized estimating equation. Different from only the mean penalized estimating equation in Johnson, Lin, and Zeng (2008), the proposed approximate zero-crossing estimator is for both the mean and the covariance robust penalized estimating equations.

Denote

$$
U^{R}(\theta)=\left(\left[U_{1}^{R}(\beta)\right]^{T},\left[U_{2}^{R}(\gamma)\right]^{T},\left[U_{3}^{R}(\lambda)\right]^{T}\right)^{T}
$$

where

$$
\begin{align*}
U_{1}^{R}(\beta) & =\sum_{i=1}^{m} X_{i}^{T}\left(V_{i}^{\beta}\right)^{-1} h_{i}^{\beta}\left(\mu_{i}(\beta)\right)  \tag{S1.1}\\
U_{2}^{R}(\gamma) & =\sum_{i=1}^{m} T_{i}^{T}\left(V_{i}^{\gamma}\right)^{-1} h_{i}^{\gamma}\left(\hat{r}_{i}(\gamma)\right)  \tag{S1.2}\\
U_{3}^{R}(\lambda) & =\sum_{i=1}^{m} Z_{i}^{T} D_{i}\left(V_{i}^{\lambda}\right)^{-1} h_{i}^{\lambda}\left(\sigma_{i}^{2}(\lambda)\right) . \tag{S1.3}
\end{align*}
$$

The following assumptions are required to establish asymptotic properties.
(C.1) The covariate vectors are fixed. Also, for each subject the number of repeated measurements, $n_{i}$, is fixed.
(C.2) The design matrices in the joint models are all bounded, meaning that all the elements of the matrices are bounded by a single finite real number. The first four moments of $y_{i j}$ exist.
(C.3) The random functions $U^{R}(\cdot)$ satisfy Lipschitz condition, that is, there exists a measurable function $m(\cdot)$ such that, $\left\|U^{R}\left(\theta_{1}, \cdot\right)-U^{R}\left(\theta_{2}, \cdot\right)\right\| \leq m(\cdot)\left\|\theta_{1}-\theta_{2}\right\|$, for every $\theta_{1}, \theta_{2}$ in the neighborhood of $\theta_{0}$, where $\int m^{2}(\cdot) d P<\infty$.
(C.4) For some $\delta>0$, we assume

$$
\sup _{i}\left\{E\left\|h_{0 i}^{\beta}\left(\mu_{i}\right)\right\|^{2+\delta}, E\left\|h_{0 i}^{\gamma}\left(\hat{r}_{i}\right)\right\|^{2+\delta}, E\left\|h_{0 i}^{\lambda}\left(\sigma_{i}^{2}\right)\right\|^{2+\delta}\right\}<\infty,
$$

where $h_{0 i}(\cdot)$ is similar to $h_{i}(\cdot)$ but the former is evaluated at the true value of parameters. Moreover,

$$
E h_{0 i}^{\beta}\left(\mu_{i}\right) h_{0 i}^{\beta}\left(\mu_{i}\right)^{T}=F_{i}^{\beta}>0, E h_{0 i}^{\gamma}\left(\hat{r}_{i}\right) h_{0 i}^{\gamma}\left(\hat{r}_{i}\right)^{T}=F_{i}^{\gamma}>0, E h_{0 i}^{\lambda}\left(\sigma_{i}^{2}\right) h_{0 i}^{\lambda}\left(\sigma_{i}^{2}\right)^{T}=F_{i}^{\lambda}>0
$$

with $\sup _{i}\left\{\left\|F_{i}^{\beta}\right\|,\left\|F_{i}^{\gamma}\right\|,\left\|F_{i}^{\lambda}\right\|\right\}<\infty$.
(C.5) The function $C_{i}^{\beta}\left(\mu_{i}\right)=E\left[\psi\left(A_{i}^{-1 / 2}\left(y_{i}-\mu_{i}\right)\right)\right], C_{i}^{\gamma}\left(\hat{r}_{i}\right)=E\left[\psi\left(D_{i}^{-1 / 2}\left(r_{i}-\hat{r}_{i}\right)\right)\right]$ and $C_{i}^{\lambda}\left(\sigma_{i}^{2}\right)=E\left[\psi\left(\widetilde{A}_{i}^{-1 / 2}\left(\varepsilon_{i}^{2}-\sigma_{i}^{2}\right)\right)\right]$ has bounded second derivative. The functions $\psi(\cdot)$ is piecewise twice differentiable, and the second derivatives are bounded.
(C.6) (a) For SCAD penalty we assume the tuning parameters $\tau_{m}^{\beta}, \tau_{m}^{\gamma}$ and $\tau_{m}^{\lambda}$ satisfying $\tau_{m} \rightarrow 0, \sqrt{m} \tau_{m} \rightarrow \infty$ when $m \rightarrow \infty$.
(b) For ALASSO penalty we assume the tuning parameters $\tau_{m}^{\beta}, \tau_{m}^{\gamma}$ and $\tau_{m}^{\lambda}$ satisfying $\sqrt{m} \tau_{m} \rightarrow 0, m \tau_{m} \rightarrow \infty$ when $m \rightarrow \infty$.

By (C.3), the convergence is uniform about $\theta$ in the neighborhood of $\theta_{0}$. (C.4) and (C.5) imposed on the score function $\psi$ can be easily checked to be satisfied when $\psi$ is bounded as that in section 2.2. (C.6) guarantees the oracle properties when we use SCAD or ALASSO penalty.

## Proof of Theorem 1.

The proof is a generalization of that in Johnson, Lin, and Zeng (2008). On one hand, we propose three estimating equations for parameters in the mean regression model together with the decomposed covariance matrices. Moreover, we robustify the three penalized estimating equations.

To prove (a) in Theorem 1, we verify that $\hat{\theta}=\left(\hat{\theta}^{s_{1} T}, 0^{T}\right)^{T}$ is an approximate zerocrossing estimator for $U(\cdot)$, where $\hat{\theta}^{s_{1}}=\theta_{0}^{s_{1}}-m^{-1}\left(G^{s_{1}}\right)^{-1} U_{s_{1}}^{R}\left(\theta_{0}\right)$. Here $U_{s_{1}}(\cdot)$ and $U_{s_{1}}^{R}(\cdot)$ denote the nonzero $s_{1}$-components of $U(\cdot)$ and $U^{R}(\cdot)$.

The following result

$$
\begin{equation*}
\sup _{\left\|\theta-\theta_{0}\right\|<M m^{-1 / 2}}\left\|m^{-1 / 2} U^{R}(\theta)-m^{-1 / 2} U^{R}\left(\theta_{0}\right)-m^{1 / 2} G_{m}\left(\theta-\theta_{0}\right)\right\|=o_{p}(1), \tag{S1.4}
\end{equation*}
$$

was assumed in Johnson, Lin, and Zeng (2008). It can also be obtained by our conditions (C.3) and (C.4), because (C.3) indicates that $\left\{U(\theta): \theta \in \Theta, \Theta \subseteq R^{p+q+d}\right\}$ is a Donsker class of empirical process and the convergence is uniform about $\theta$ in the neighborhood of $\theta_{0}$.

Meanwhile, conditions for multivariate Lyapunov central limit theorem for $U_{\theta}^{R}$ can be verified by the conditions (C.3)-(C.5) we imposed, i.e, $m^{-1 / 2}\left(G^{s_{1}}\right)^{-1} U_{s_{1}}^{R}\left(\theta_{0}\right) \rightarrow$ $N_{s_{1}}\left(0,\left(G^{s_{1}}\right)^{-1} B^{s_{1}}\left[\left(G^{s_{1}}\right)^{T}\right]^{-1}\right)$, as $n \rightarrow \infty$ in distribution.

Therefore under (S1.4) and $\hat{\theta}=\theta_{0}+O_{p}\left(m^{-1 / 2}\right)$, we have

$$
m^{-1 / 2} U_{j}\left(\hat{\theta} \pm \varepsilon e_{j}\right)=o_{p}(1)-m^{-1 / 2} q_{\tau_{m}}\left(\left|\hat{\theta}_{j} \pm \varepsilon\right|\right) \operatorname{sgn}\left(\left|\hat{\theta}_{j} \pm \varepsilon\right|\right), \quad j=1, \ldots, s_{1}
$$

where $U_{j}(\cdot)$ is the $j$ th component of $U(\cdot)$.
Under condition (a) in (C.6), for any nonzero fixed $\theta \in \Theta$, we have $\lim _{m \rightarrow \infty} \sqrt{m} q_{\tau_{m}}(|\theta|)=$ $\lim _{m \rightarrow \infty} q_{\tau_{m}}^{\prime}(|\theta|)=0$ for SCAD penalty. For ALASSO penalty, given condition (b) in (C.6) we conclude $\sqrt{m} q_{\tau_{m}}(|\theta|)=\sqrt{m} \tau_{m} /|\tilde{\theta}| \rightarrow 0$ if $1 /|\tilde{\theta}|<\infty$ and $q_{\tau_{m}}^{\prime}(|\theta|)=0$, where $\tilde{\theta}$ stands for the regression coefficient estimates obtained from $U^{R}(\theta)$ (without penalty). As a consequence, for any $\varepsilon \rightarrow 0^{+}, m^{-1 / 2} U_{j}\left(\hat{\theta} \pm \varepsilon e_{j}\right)=o_{p}(1), j=1, \ldots, s_{1}$.

Furthermore, for SCAD and any $M>0, \sqrt{m} \inf _{|\theta| \leq M m^{-1 / 2}} q_{\tau_{m}}(|\theta|)=\sqrt{m} \tau_{m} \rightarrow \infty$. When $\sqrt{m}\left(\tilde{\theta}-\theta_{0}\right)=O_{p}(1)$ under some conditions, then $\sqrt{m} \inf _{|\theta| \leq M m^{-1 / 2}} q_{\tau_{m}} /|\tilde{\theta}|=$ $M^{-1} m \tau_{m} \rightarrow \infty$ for ALASSO. Therefore, for $j=s_{1}+1, \ldots, s, \hat{\theta}_{j}=0, m^{-1 / 2} U_{j}\left(\hat{\theta}+\varepsilon e_{j}\right)$ and $m^{-1 / 2} U_{j}\left(\hat{\theta}-\varepsilon e_{j}\right)$ are dominated by $-m^{-1 / 2} q_{\tau_{m}}(\varepsilon)$ and $m^{-1 / 2} q_{\tau_{m}}(\varepsilon)$ with opposite signs when $\varepsilon \rightarrow 0$. As a result, we conclude that $\hat{\theta}$ is an approximate zero-crossing estimator by its definition.

We denote $\hat{\theta}=\left(\hat{\theta}_{1}, \ldots \hat{\theta}_{s}\right)^{T}$ as $\sqrt{m}$ consistent approximate zero-crossing solution of $U(\theta)=0$. To prove (b) in Theorem 1, we need to show that for any $\varepsilon>0$, when $m$ is sufficiently large,

$$
P\left\{\hat{\theta}_{j} \neq 0, j=s_{1}+1, \ldots, s\right\}<\varepsilon
$$

On one hand, for $j=s_{1}+1, \ldots, s$, there exists some $M>0$ such that when $m$ is large enough, $P\left\{\hat{\theta}_{j} \neq 0, j=s_{1}+1, \ldots, s,\left|\hat{\theta}_{j}\right| \geq M m^{-1 / 2}\right\}<\varepsilon / 2$. Therefore, we only need to show that $P\left\{\hat{\theta}_{j} \neq 0, j=s_{1}+1, \ldots, s,\left|\hat{\theta}_{j}\right|<M m^{-1 / 2}\right\}<\varepsilon / 2$ when $m$ is large enough.

As shown in Johnson, Lin, and Zeng (2008), $\left[m^{-1 / 2} U_{j}(\hat{\theta})\right]^{2}=o_{p}(1)$ and there exists some $M^{\prime}>0$ such that for large m ,

$$
P\left\{\hat{\theta}_{j} \neq 0, j=s_{1}+1, \ldots, s,\left|\hat{\theta}_{j}\right|<M m^{-1 / 2}, m^{1 / 2} q_{\tau_{m}}\left(\left|\hat{\theta}_{j}\right|\right)>M^{\prime}\right\}<\varepsilon / 2
$$

Because for any $M>0, \lim _{m \rightarrow \infty} \sqrt{m} \inf _{|\theta| \leq M m^{-1 / 2}} q_{\tau_{m}}(|\theta|) \rightarrow \infty$, by condition (C.6), $\hat{\theta}_{j} \neq 0, j=s_{1}+1, \ldots, s,|\hat{\theta}|_{j}<M m^{-1 / 2}$ implies that $m^{-1 / 2} q_{\tau_{m}}\left(\left|\hat{\theta}_{j}\right|\right)>M^{\prime}$ for large $m$. Thus $P\left\{\hat{\theta}_{j} \neq 0, j=s_{1}+1, \ldots, s,\left|\hat{\theta}_{j}\right|<M m^{-1 / 2}\right\}<\varepsilon / 2$ and Theorem 1 (b) has been proved.

## Proof of Theorem 2.

We apply the Taylor series expansion on the last term of

$$
m^{-1 / 2} U_{s_{1}}^{R}\left(\theta_{0}\right)+m^{1 / 2} G^{s_{1}}\left(\hat{\theta}^{s_{1}}-\theta_{0}^{s_{1}}\right)-m^{1 / 2} q_{\tau_{m}}\left(\left|\hat{\theta}^{s_{1}}\right|\right) \operatorname{sgn}\left(\hat{\theta}^{s_{1}}\right)=o_{p}(1)
$$

and rearranged by $c_{m}=\left(q_{\tau_{m}}\left(\left|\theta_{01}^{s_{1}}\right|\right) \operatorname{sgn}\left(\theta_{01}^{s_{1}}\right), \ldots, q_{\tau_{m}}\left(\left|\theta_{0 s_{1}}^{s_{1}}\right|\right) \operatorname{sgn}\left(\theta_{0 s_{1}}^{s_{1}}\right)\right)^{T}$ and $\Omega_{m}^{s_{1}}$ to obtain that

$$
\sqrt{m}\left(G_{m}^{s_{1}}+\Omega_{m}^{s_{1}}\right)\left\{\hat{\theta}_{m}^{s_{1}}-\theta_{0}^{s_{1}}+\left(G_{m}^{s_{1}}+\Omega_{m}^{s_{1}}\right)^{-1} c_{m}\right\} \rightarrow_{d} N_{s_{1}}\left(0, B^{s_{1}}\right)
$$

For any nonzero fixed $\theta \in \Theta$, under conditions (a) and (b) in (C.6), $\lim _{m \rightarrow \infty} \sqrt{m} q_{\tau_{m}}(|\theta|)=$ $\lim _{m \rightarrow \infty} q_{\tau_{m}}^{\prime}(|\theta|)=0$ for SCAD penalty and $\sqrt{m} q_{\tau_{m}}(|\theta|)=\sqrt{m} \tau_{m} /|\tilde{\theta}| \rightarrow 0$ if $1 /|\tilde{\theta}|<\infty$ and $q_{\tau_{m}}^{\prime}(|\theta|)=0$ for ALASSO penalty, where $\tilde{\theta}$ stands for the regression coefficient estimates obtained from $U^{R}(\theta)$ (without penalty). Therefore, $c_{m}$ tends to zero for both SCAD and ALASSO penalized estimators as $m \rightarrow \infty$.

## S2 An algorithm

We describe the algorithm for estimating $\beta, \gamma$ and $\lambda$ simultaneously. The iterative MM algorithm can be written as:

$$
\begin{aligned}
& \beta^{(k+1)}=\beta^{(k)}+\left[G\left(\beta^{(k)}\right)+\Delta_{\tau^{(1)}}\left(\beta^{(k)}\right)\right]^{-1} U_{1}\left(\beta^{(k)}\right) \\
& \gamma^{(k+1)}=\gamma^{(k)}+\left[G\left(\gamma^{(k)}\right)+\Delta_{\tau^{(2)}}\left(\gamma^{(k)}\right)\right]^{-1} U_{2}\left(\gamma^{(k)}\right) \\
& \lambda^{(k+1)}=\lambda^{(k)}+\left[G\left(\lambda^{(k)}\right)+\Delta_{\tau^{(3)}}\left(\lambda^{(k)}\right)\right]^{-1} U_{3}\left(\lambda^{(k)}\right)
\end{aligned}
$$

where $G(\beta), G(\gamma)$ and $G(\lambda)$ are $p \times p, q \times q$ and $d \times d$ submatrices of $G$ corresponding to the parameters, and

$$
\Delta_{\tau^{(1)}}(\beta)=\operatorname{diag}\left(\frac{q_{\tau^{(1)}}\left(\left|\beta_{1}\right|\right)}{\varepsilon_{p}+\left|\beta_{1}\right|}, \cdots, \frac{q_{\tau^{(1)}}\left(\left|\beta_{p}\right|\right)}{\varepsilon_{p}+\left|\beta_{p}\right|}\right)
$$

$\Delta_{\tau^{(2)}}(\gamma)=\operatorname{diag}\left(\frac{q_{\tau^{(2)}}\left(\left|\gamma_{1}\right|\right)}{\varepsilon_{p}+\left|\gamma_{1}\right|}, \cdots, \frac{q_{\tau^{(2)}}\left(\left|\gamma_{q}\right|\right.}{\varepsilon_{p}+\left|\gamma_{q}\right|}\right), \Delta_{\tau^{(3)}}(\lambda)=\operatorname{diag}\left(\frac{q_{\tau^{(3)}}\left(\left|\lambda_{1}\right|\right)}{\varepsilon_{p}+\left|\lambda_{1}\right|}, \cdots, \frac{q_{\tau^{(3)}}\left(\left|\lambda_{d}\right|\right)}{\varepsilon_{p}+\left|\lambda_{d}\right|}\right)$.
Here $\varepsilon_{p}$ is a fixed small number for the purpose of preventing computational singular, and chosen to be $10^{-6}$ in our simulation.

Convenient initial values for the covariance parameters are $\gamma=0$ and $\lambda=0$, which indicate independence structure in the covariance matrix. A natural choice of the initial estimate $\beta^{(0)}$ of $\beta$ is the solution to (2.2) in this special case as the robust GEE estimator under working independence covariance structure, whose consistency has been proved. The following algorithm summarizes the computation of the penalized GEE estimators for joint mean and covariance model.
Algorithm:

0 . Take zeros as initial values of $\gamma$ and $\lambda$, that is $\gamma^{(0)}$ and $\lambda^{(0)}$. Then take $\beta^{(0)}$ as the the solution to (2.2) with independent working matrix.

1. Given current $\left\{\beta^{(k)}, \gamma^{(k)}, \lambda^{(k)}\right\}$, use the MM algorithm to update $\gamma$ and $\lambda$ until convergence, which are denoted as $\gamma^{(k+1)}$ and $\lambda^{(k+1)}$.
2. For the updated $\gamma^{(k+1)}$ and $\lambda^{(k+1)}$, form

$$
\phi_{i j k}^{(k+1)}=g_{i j k}^{T} \gamma^{(k+1)}, \text { and }\left(\sigma_{i j}^{2}\right)^{(k+1)}=\exp \left(z_{i j}^{T} \lambda^{(k+1)}\right)
$$

to construct

$$
\Sigma_{i}^{(k+1)}=\left(\Phi_{i}^{(k+1)}\right)^{-1} D_{i}^{(k+1)}\left[\left(\Phi_{i}^{(k+1)}\right)^{T}\right]^{-1}
$$

Then update $\beta$ according to the MM algorithm to obtain $\beta^{(k+1)}$.
3. Repeat Step 1 and Step 2 above until convergence.

This widely-used algorithm (the non-robust version, i.e. the tuning parameter of Huber function $c$ is set to a very large value) has been proved to be well performed under the usual case (no outliers) by Kou and Pan (2011). However, in our simulation, we find the non-robust algorithm behaves poorly when there are outliers. Since the joint mean and covariance model introduces more parameters than GEE, the algorithm based on the non-robust penalized estimating equations faces a great challenge to obtain a reliable estimator when the contamination can happen in any of three estimating equations. Even a tiny contamination can result in non-convergence or estimation with a large bias. In contrast, the robust algorithm performs fairly well against perturbations.

## S3 Standard errors and losses of covariance matrix estimators in Studies 1 and 2

To judge the performance of the proposed covariance estimator, we introduce two commonly used loss functions: the entropy loss

$$
L_{1}(\Sigma, \hat{\Sigma})=m^{-1} \sum_{i=1}^{m}\left\{\operatorname{trace}\left(\Sigma_{i} \hat{\Sigma}_{i}^{-1}\right)-\log \left|\Sigma \hat{\Sigma}_{i}^{-1}\right|-n_{i}\right\}
$$

and the quadratic loss

$$
L_{2}(\Sigma, \hat{\Sigma})=m^{-1} \sum_{i=1}^{m} \operatorname{trace}\left(\Sigma_{i}^{-1} \hat{\Sigma}_{i}-I_{i}\right)^{2}
$$

where $\Sigma_{i}$ and $\hat{\Sigma}_{i}$ are the true covariance matrix and its estimator.
