a bounded gradient. In Algorithms\cite{2016} the bound of the minibatch gradients is $C/m$ after clipping. Consequently, the result follows from Theorem 1 in \cite{Abadi2016}.

\textbf{Lemma 1} (Lemma 8 in \cite{Atchadé2017}). Assume that $\gamma \in (0, K^{-1}_1]$. Then under Assumption (A1), for all $\beta, \beta', \omega \in \mathcal{B}$,

$$-2\gamma \left( F_{\mathcal{D}}(\text{prox}_{\gamma, g}(\beta)) - F_{\mathcal{D}}(\beta') \right) \geq \|\text{prox}_{\gamma, g}(\beta) - \beta'\|^2$$

$$+ 2 \left< \text{prox}_{\gamma, g}(\beta) - \beta', \omega - \gamma \nabla L_{\mathcal{D}}(\omega) - \beta \right> - \|\beta' - \omega\|^2.$$

\textbf{Proof of Theorem 4.2}. By Jensen’s inequality,

$$\mathbb{E}[F_{\mathcal{D}}(\beta^T) - F_{\mathcal{D}}(\beta^*)] \leq \mathbb{E} \left[ T^{-1} \sum_{t=1}^{T} (F_{\mathcal{D}}(\beta_t) - F_{\mathcal{D}}(\beta^*)) \right].$$

Firstly, we consider a single step by taking $\beta = \beta_{t-1} - \gamma_{t-1} \nabla \hat{L}_{\mathcal{D}}(\beta_{t-1}),$
\[ \omega = \beta_{t-1}, \quad \beta' = \beta^*, \quad \text{and} \quad \gamma = \gamma_{t-1} \text{ in Lemma 1, which yields that} \]

\[
F_D(\beta_t) - F_D(\beta^*) \\
\leq \frac{1}{2\gamma_{t-1}} (\|\beta_{t-1} - \beta^*\|^2 - \|\beta_t - \beta^*\|^2) + \langle \beta_t - \beta^*, \nabla L_D(\beta_{t-1}) - \nabla \tilde{L}_D(\beta_{t-1}) \rangle \\
\leq \frac{\Delta^2}{2\gamma_{t-1}} + \langle \beta_t - \beta^*, \nabla L_D(\beta_{t-1}) - \nabla \tilde{L}_D(\beta_{t-1}) \rangle,
\]

where the second inequality holds by Assumption (A2).

Summing for \( t = 1, \ldots, T \), we have

\[
\sum_{t=1}^{T} [F_D(\beta_t) - F_D(\beta^*)] \leq \frac{\Delta^2}{2\gamma_{T-1}} + \sum_{t=1}^{T} \langle \beta_t - \beta^*, \nabla L_D(\beta_{t-1}) - \nabla \tilde{L}_D(\beta_{t-1}) \rangle.
\]

Then,

\[
\mathbb{E}[F_D(\beta_T) - F_D(\beta^*)] \\
\leq \frac{\Delta^2}{2T\gamma_{T-1}} + \frac{1}{T} \sum_{t=1}^{T} \mathbb{E}[\langle \beta_t - \beta^*, \nabla L_D(\beta_{t-1}) - \nabla \tilde{L}_D(\beta_{t-1}) \rangle] \\
\leq \frac{\Delta^2}{2T\gamma_{T-1}} + \frac{\Delta}{T} \sum_{t=1}^{T} \text{Bias}_{\mathbb{E}}(\nabla \tilde{L}_{t-1}),
\]

where the second inequality comes from the H"{o}lder’s inequality. \( \square \)

S2.2 Proofs for Algorithm 2

Lemma 2 (Lemma 13 in Kamath et al. (2020)). Let \( \mathcal{X} \) be a distribution over \( \mathbb{R} \) with mean \( \mu \). Suppose that \( x \sim \mathcal{X} \) and that \( \mathbb{E}[|x - \mu|^k] \leq 1 \) for some
$k \geq 2$. Furthermore, for any $c \in \mathbb{R}$, define

$$Z = \begin{cases} 
  c - \varrho/2, & x < c - \varrho/2 \\
  c + \varrho/2, & x > c + \varrho/2 \\
  x, & \text{else}.
\end{cases}$$

If $|\mu - c| \leq \varrho/4$, then $|\mu - \mathbb{E}[Z]| \leq 8(4/\varrho)^{k-1}$.

**Proof of Theorem 5.1.** For any $j \in [p]$ and $x \in Z^i_j$ (defined in Algorithm 3), by Hölder’s inequality,

$$\mathbb{E}(x - \mathbb{E}[Z_j])^2 \leq \mathbb{E}[|x - \mathbb{E}[Z_j]|^k]^{2/k} \leq 1$$

for any fixed $i \in [q]$. The second inequality holds under the assumption that

$$\mathbb{E}[|\langle X - \mu, e_j \rangle|^k] \leq 1$$

for $X \sim \mathcal{P}$.

Now, since

$$\mathbb{E}[\hat{\mu}_j - \mathbb{E}[Z_j]]^2 = \mathbb{E}\left[\frac{q}{n} \sum_{x \in Z^i_j} x - \mathbb{E}[Z_j]\right]^2$$

$$= \frac{q^2}{n^2} \mathbb{E}\left[\sum_{x \in Z^i_j} x - \frac{n^2}{q^2} \mathbb{E}[Z_j]\right]^2$$

$$= \frac{q^2}{n^2} \mathbb{E}\left[\sum_{x \in Z^i_j} (x - \mathbb{E}[Z_j])^2\right]$$

$$\leq \frac{q}{n},$$

Chebyshev’s inequality implies that

$$\mathbb{P}\left[|\hat{\mu}_j - \mathbb{E}[Z_j]| \leq 10\sqrt{\frac{q}{n}} \right] \geq 0.9.$$
Recall that $\hat{\mu}_j = \text{Median}\{\hat{\mu}^i_j, \ldots, \hat{\mu}^q_j\}$. Let $Y_i = 1(|\hat{\mu}_j - \mathbb{E}[Z_j]| \geq 10\sqrt{q/n})$. The $Y_i$s are i.i.d. Bernoulli random variables with a success probability of at most $1/10$. It follows that

$$\mathbb{P}\left[|\hat{\mu}_j - \mathbb{E}[Z_j]| \geq 10\sqrt{q/n}\right] = \mathbb{P}\left[\sum_{i=1}^q Y_i \geq \frac{q}{2}\right] = \mathbb{P}\left[\sum_{i=1}^q (Y_i - \frac{1}{10}) \geq \frac{2q}{5}\right].$$

By Hoeffding’s inequality,

$$\mathbb{P}\left[|\hat{\mu}_j - \mathbb{E}[Z_j]| \geq 10\sqrt{q/n}\right] \leq \exp(-q/3).$$

Recall that $\hat{\mu} = (\hat{\mu}_1, \ldots, \hat{\mu}_p)^T + \mathcal{N}(0, \sigma^2 I_p)$, where $\sigma = q\sqrt{p\log(\delta^{-1})}/(n\epsilon)$.

By Lemma 2 and the tail properties of the chi-squared distribution, with probability no less than $1 - \zeta$,

$$\|\hat{\mu} - \mu\| \leq O\left(\frac{q\log(p/\zeta)\sqrt{p\log(\delta^{-1})}}{n\epsilon}\left(\sqrt{p} + \sqrt{\log(\zeta^{-1})}\right)\right.$$

$$\left. + \sqrt{p}\left(\sqrt{\frac{\log(p/\zeta)}{n}} + \left(\frac{4}{\theta}\right)^{k-1}\right)\right),$$

if we take $q = 3\log(2p/\zeta)$ and $\theta \geq 4\|\mu\|_{\infty}$. \hfill \Box

**Lemma 3.** For Algorithm 2, under Assumptions (A2)–(A5), with probability at least $1 - \zeta$,

$$\|\nabla \hat{L}_D(\beta) - \nabla L_D(\beta)\| \leq \tilde{O}\left(p^{\frac{3}{2}}\log(\zeta^{-1})\left(\frac{\sqrt{p\log(\delta^{-1})}}{m\epsilon}\right)^{\frac{k-1}{k}}\right)$$

for any $\beta \in \mathcal{B}$.

**Proof of Lemma 3.** Since $\mathcal{B}$ is closed and bounded, it is compact. The number of balls of radius $\xi$ required to cover $\mathcal{B}$ is bounded above as $N_\xi \leq \ldots$
\[(3\Delta/2\xi)^p \text{ [Tikhomirov, 1993]. Let } \tilde{\beta} \in \{\tilde{\beta}_1, \ldots, \tilde{\beta}_{N_\xi}\} \text{ be any center of this } \xi\text{-net. It follows that}
\]

\[
\|\nabla \hat{L}_D(\beta) - \nabla L_D(\beta)\| \leq \|\nabla \hat{L}_D(\beta) - \nabla \hat{L}_D(\tilde{\beta})\| + \|\nabla \hat{L}_D(\tilde{\beta}) - \nabla L_D(\tilde{\beta})\|
\]

\[
+ \|\nabla L_D(\tilde{\beta}) - \nabla L_D(\beta)\|.
\]

Then we handle each component separately.

For the first term, let \(N \sim \mathcal{N}(0, \sigma^2 I_p)\), where \(\sigma = \varrho q \sqrt{p \log(\delta^{-1})}/(m\epsilon)\), we have

\[
\|\nabla \hat{L}_D(\beta) - \nabla \hat{L}_D(\tilde{\beta})\| \leq \sqrt{\sum_{j=1}^p \left( \hat{\mu}_j(\beta) - \hat{\mu}_j(\tilde{\beta}) \right)^2 + 2\|N\|}
\]

\[
= \sqrt{\sum_{j=1}^p \left( \frac{q}{m} \sum_{k=1}^{m/q} |\nabla \ell_{kj}(\beta) - \nabla \ell_{kj}(\tilde{\beta})| \right)^2 + 2\|N\|}
\]

\[
\leq \sqrt{pK_2\|\beta - \tilde{\beta}\| + 2\|N\|}.
\]

Since

\[
\mathbb{P}\left(\|N\| \leq 2\sigma(\sqrt{p} + \sqrt{\log(1/2\zeta)})\right) > 1 - \zeta,
\]

with probability at least \(1 - \zeta\),

\[
\|\nabla \hat{L}_D(\beta) - \nabla \hat{L}_D(\tilde{\beta})\| \leq O\left(\sqrt{p}\|\beta - \tilde{\beta}\| + \frac{qgp \log^{1/2}(\delta^{-1}) \log(\zeta^{-1})}{m\epsilon}\right)
\]

\[
\leq \tilde{O}\left(\sqrt{p}\|\beta - \tilde{\beta}\| + \sqrt{p} \log(\zeta^{-1}) \left(\frac{\sqrt{p \log(\delta^{-1})}}{m\epsilon}\right)^{k^{-1}}\right),
\]

where the notation \(\tilde{O}\) omits some logarithmic terms.
Next is to bound the second term. From Theorem 5.1, we know for any center \( \tilde{\beta}(\beta) \),

\[
\| \nabla \hat{L}_D(\tilde{\beta}) - \nabla L_D(\tilde{\beta}) \| \leq O \left( \frac{\rho \log \left( \frac{p}{\zeta} \right) \sqrt{p \log(\delta^{-1})}}{m\epsilon} \left( \sqrt{p} + \sqrt{\log(\zeta^{-1})} \right) \right.
\]

\[
\left. + \sqrt{p} \left( \frac{\log \left( \frac{p}{\zeta} \right)}{m} + \left( \frac{4}{\rho} \right)^{k-1} \right) \right)
\]

with probability at least \( 1 - \zeta \). The \( \xi \)-net for \( B \) circumvents the need to take a supremum over \( \beta \in B \) as

\[
\sup_{\beta \in B} \| \nabla \hat{L}_D(\tilde{\beta}(\beta)) - \nabla L_D(\tilde{\beta}(\beta)) \|
\]

\[
= \max_{k \in N_\xi} \| \nabla \hat{L}_D(\tilde{\beta}_k) - \nabla L_D(\tilde{\beta}_k) \|
\]

\[
\leq O \left( \frac{\rho \log \left( pN_\xi \zeta^{-1} \right) \sqrt{p \log(\delta^{-1})}}{m\epsilon} \left( \sqrt{p} + \sqrt{\log(\zeta^{-1})} \right) + \sqrt{p} \left( \frac{\log \left( pN_\xi \zeta^{-1} \right)}{m} + \left( \frac{4}{\rho} \right)^{k-1} \right) \right)
\]

\[
\leq \tilde{O} \left( p^{\frac{3}{2}} \log(\zeta^{-1}) \left( \frac{\sqrt{p \log(\delta^{-1})}}{m\epsilon} \right)^{\frac{k-1}{k}} \right)
\]

According to Assumption (A3), the third term \( \| \nabla L_D(\tilde{\beta}) - \nabla L_D(\beta) \| \leq K_1 \| \tilde{\beta} - \beta \|. \)

To sum up,

\[
\sup_{\beta \in B} \| \nabla \hat{L}_D(\beta) - \nabla L_D(\beta) \|
\]

\[
\leq \tilde{O} \left( \sqrt{p} \| \beta - \tilde{\beta} \| + p^{\frac{3}{2}} \log(\zeta^{-1}) \left( \frac{\sqrt{p \log(\delta^{-1})}}{m\epsilon} \right)^{\frac{k-1}{k}} \right)
\]

with probability \( 1 - \zeta \). Setting \( \xi = m^{\frac{1}{2-k}} \) directly yields Lemma 3. \qed
Proof of Corollary 5.2. We will begin by demonstrating that Algorithm 2 satisfies the DP guarantee. This can be directly inferred from the proof of Proposition 4.1, with minibatch gradients bounded by $\rho q \sqrt{p/m}$. Subsequently, we will derive an upper bound on the excess population risk with high probability:

\[
F_D(\bar{\beta}^T) - F_D(\beta^*) \leq \frac{1}{T} \sum_{t=1}^{T} \left[ \frac{1}{2\gamma_t} (\|\beta_{t-1} - \beta^*\|^2 - \|\beta_t - \beta^*\|^2) + \langle \beta_t - \beta^*, \nabla L_D(\beta_{t-1}) - \nabla \widehat{L}_D(\beta_{t-1}) \rangle \right] \leq \frac{\Delta^2}{2T\gamma_{T-1}} + T\sum_{t=1}^{T} \langle \beta_t - \beta^*, \nabla L_D(\beta_{t-1}) - \nabla \widehat{L}_D(\beta_{t-1}) \rangle \leq \frac{\Delta^2}{2T\gamma_{T-1}} + \tilde{O}\left(\frac{p^2 \log(\zeta^{-1})}{\log(\zeta^{-1})} \left( \frac{\sqrt{p \log(\delta^{-1})}}{m\epsilon} \right)^{k+1} \right)
\]

with probability at least $1 - \zeta$. The first inequality holds by Lemma 1 while the second holds by Assumption (A2). The last inequality follows from the Hölder’s inequality and Lemma 3.

S2.3 Proofs for Algorithm 4

Lemma 4 (Theorem 2 in [Wang et al. (2020)]). Let $X_1, X_2, \ldots, X_n$ be i.i.d. samples from some distribution $\Theta$. Assume that that $\mathbb{E}_{X \sim \Theta}[X^2] \leq \tau$ for some known $\tau$. Let $\nu = \sqrt{\log(\zeta^{-1})}$ and $s = \sqrt{n\epsilon\tau/(\log(\zeta^{-1}) \log^{1/4}(\delta^{-1}))}$
for a given failure probability $\zeta$. Then with probability at least $1 - \zeta$,

$$|\mathcal{A}(D) - \mathbb{E}[X]| \leq O\left(\sqrt{\frac{\tau \log^{1/2}(\delta^{-1}) \log(\zeta^{-1})}{n\epsilon}}\right).$$

**Lemma 5** (Lemma 7 in [Holland (2019)]). The estimator $\hat{x}$ defined in (5.3) as a function of the data $(x_1, \ldots, x_n)^\top \in \mathbb{R}^n$ satisfies

$$|\hat{x}(x) - \hat{x}(x')| \leq \frac{c_x}{n}\|x - x'\|_1,$$

where the factor $c_x$ takes the form

$$c_x = 1 - 2\Phi(-\sqrt{\nu}) + \sqrt{2 \nu \pi} \exp\left(-\frac{\nu}{2}\right)$$

and where $\Phi$ is the cumulative distribution function for the standard normal distribution.

**Proof of Theorem 5.3** As the proof of Lemma 3 we apply the standard strategy of covering to obtain the uniform upper bound of the error term $\|\nabla \hat{L}_D(\beta) - \nabla L_D(\beta)\|$. By triangle inequality, we decompose it into three components:

$$\|\nabla \hat{L}_D(\beta) - \nabla L_D(\beta)\| \leq \|\nabla \hat{L}_D(\beta) - \nabla \hat{L}_D(\tilde{\beta})\| + \|\nabla \hat{L}_D(\tilde{\beta}) - \nabla L_D(\tilde{\beta})\|$$

$$+ \|\nabla L_D(\tilde{\beta}) - \nabla L_D(\beta)\|,$$

where $\tilde{\beta} \in \{\tilde{\beta}_1, \ldots, \tilde{\beta}_{N_\xi}\}$ is any center of a $\xi$-net. Then we handle each component separately.
We first deal with the last term. By Assumption (A3),
\[
\|\nabla L_D(\tilde{\beta}) - \nabla L_D(\beta)\| \leq K_1\|\tilde{\beta} - \beta\|
\]
Regarding the first term, let \( N \sim N(0, \sigma^2 I_p) \), where \( \sigma = 4sp\sqrt{\frac{2p\log(\delta^{-1})}{(3m\epsilon)}} \), we have \( \nabla L_D(\beta) = \tilde{\ell}(\beta) + N \) in Algorithm 4 (line 6), so
\[
\|\nabla L_D(\beta) - \nabla L_D(\tilde{\beta})\| \leq \|\tilde{\ell}(\beta) - \tilde{\ell}(\tilde{\beta})\| + 2\|N\|
\]
In accordance with the tail property of chi-squared distribution,
\[
P\left(\|N\| \leq 2\sigma(\sqrt{p} + \sqrt{\log(\frac{1}{2\zeta})})\right) > 1 - \zeta.
\]
In addition, Lemma 5 yields that
\[
\|\tilde{\ell}(\beta) - \tilde{\ell}(\tilde{\beta})\|^2 \leq \sum_{j=1}^{p} \left( \frac{c}{m} \|\nabla \ell_j(\beta) - \nabla \ell_j(\tilde{\beta})\|_1 \right)^2
\]
\[
\leq \sum_{j=1}^{p} \left( \frac{c}{m} \sum_{i=1}^{m} |\nabla \ell_{ij}(\beta) - \nabla \ell_{ij}(\tilde{\beta})| \right)^2
\]
\[
\leq pc^2\chi^2 K_2^2 \|\beta - \tilde{\beta}\|^2,
\]
and so
\[
\|\tilde{\ell}(\beta) - \tilde{\ell}(\tilde{\beta})\| \leq \sqrt{pc_2^2 K_2^2} \|\beta - \tilde{\beta}\|.
\]
Therefore,
\[
\|\nabla L_D(\beta) - \nabla L_D(\tilde{\beta})\| \leq \sqrt{pc_2^2 K_2^2} \|\beta - \tilde{\beta}\| + \frac{16s\sqrt{2p\log(\delta^{-1})}}{3m\epsilon} \left( \sqrt{p} + \sqrt{\log(\frac{1}{2\zeta})} \right).
\]
To bound the second term, we apply Lemma 4. It follows that
\[
|\nabla \tilde{L}_j(\beta) - \nabla L_j(\beta)| \leq \sqrt{\frac{\tau \log^{1/2}(\delta^{-1}) \log(\zeta^{-1})}{m\epsilon}}
\]
for \( j \in [p] \) and any fixed \( \beta \) as long as \( \mathbb{E}[(\nabla_j \ell(\beta; x, y))^2] < \infty \). Hence,

\[
\mathbb{P}\left[ \|\nabla \hat{L}_D(\beta) - \nabla L_D(\beta)\| > \sqrt{\frac{p \tau \log^{1/2}(\delta^{-1}) \log(\zeta^{-1})}{m\epsilon}} \right]
\leq \sum_{j=1}^{p} \mathbb{P}\left[ \|\nabla \hat{L}_j(\beta) - \nabla L_j(\beta)\| \leq \sqrt{\frac{\tau \log^{1/2}(\delta^{-1}) \log(\zeta^{-1})}{m\epsilon}} \right]
\leq p\zeta.
\]

Let \( \tilde{\beta} = \tilde{\beta}(\beta) \) denote the closest center to any fixed \( \beta \). Thus,

\[
\|\nabla \hat{L}_D(\tilde{\beta}) - \nabla L_D(\tilde{\beta})\| > \sqrt{\frac{p \tau \log^{1/2}(\delta^{-1}) \log(p\zeta^{-1})}{m\epsilon}}
\]

occurs with probability no greater than \( \zeta \). Then

\[
\sup_{\beta \in B}\|\nabla \hat{L}_D(\tilde{\beta}(\beta)) - \nabla L_D(\tilde{\beta}(\beta))\| = \max_{k \in N_{\tilde{\beta}}}\|\nabla \hat{L}_D(\tilde{\beta}_k) - \nabla L_D(\tilde{\beta}_k)\|
\leq \sqrt{\frac{p \tau \log^{1/2}(\delta^{-1}) \log(pN_{\tilde{\beta}}\zeta^{-1})}{m\epsilon}}.
\]

Therefore, if we let

\[
\mathcal{V} = \frac{16s}{3m\epsilon} \left( \sqrt{p} + \sqrt{\frac{\log(1/2\zeta)}{2\zeta}} \right),
\]

a uniform upper bound on \( \|\nabla \hat{L}_D(\beta) - \nabla L_D(\beta)\| \) is

\[
\sup_{\beta \in B}\|\nabla \hat{L}_D(\beta) - \nabla L_D(\beta)\|
\leq \sup_{\beta \in B} \left( \sqrt{pc}K_2\|\beta - \tilde{\beta}\| + K_1\|\beta - \tilde{\beta}\| \right) + \sqrt{\frac{p \tau \log^{1/2}(\delta^{-1}) \log(pN_{\tilde{\beta}}\zeta^{-1})}{m\epsilon}} + \mathcal{V}
\leq \max\{K_1, K_2\}(\sqrt{pc} + 1) + \sqrt{\frac{p \tau \log^{1/2}(\delta^{-1}) \log(pN_{\tilde{\beta}}\zeta^{-1})}{m\epsilon}} + \mathcal{V}
\]
with probability at least 1 − ζ. Setting $s = \sqrt{m\epsilon\tau}/(\log(\zeta^{-1}) \log^{1/4}(\delta^{-1}))$ and $\xi = m^{-1/2}$ directly yield Theorem 5.3.

**Proof of Corollary 5.4.** Once the truncation step is performed, the robust gradients in Algorithm 4 are bounded by $4s\sqrt{2p/(3m)}$. As a result, it is easy to demonstrate that the privacy guarantee is met. The proof for the utility guarantee is identical to that of Corollary 5.2 but with the application of the uniform bound from Theorem 5.3.

**S2.4 Explicit form of $C(a, b)$ in Catoni and Giulini (2017)**

The correction term $C(a, b)$ can be computed as follows. First, define

\[
V_\pm = \frac{\sqrt{2} \pm a}{b}, \quad V_+ = \frac{\sqrt{2} + a}{b}, \quad F_\pm = \Phi(-V_\pm), \quad F_+ = \Phi(-V_+), \quad E_\pm = \exp\left(-\frac{V_\pm^2}{2}\right), \quad E_+ = \exp\left(-\frac{V_+^2}{2}\right),
\]

where $\Phi$ denotes the cumulative distribution function for the standard normal distribution. With these elements, we can break the final quantity into
five terms:

\[ T_1 = \frac{2\sqrt{2}}{3} (F_- - F_+) \]

\[ T_2 = - \left( a - \frac{a^3}{6} \right) (F_- + F_+) \]

\[ T_3 = \frac{b}{\sqrt{2\pi}} \left( 1 - \frac{a^2}{2} \right) (E_+ - E_-) \]

\[ T_4 = \frac{ab^2}{2} \left( F_+ + F_- + \frac{1}{\sqrt{2\pi}} (V_+ E_+ + V_- E_-) \right) \]

\[ T_5 = \frac{b^3}{6\sqrt{2\pi}} \left( (2 + V_-^2) E_- - (2 + V_+^2) E_+ \right). \]

At last, we explicitly define

\[ C(a, b) = T_1 + T_2 + T_3 + T_4 + T_5. \]

**Bibliography**

Catoni, O. and I. Giulini (2017). Dimension-free PAC-Bayesian bounds
